HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of Herpetological Review in 1967 (Corson Hirschfeld, Editor):

> "Herpetological Review incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the Review will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Now in its tenth year, Herpetological Review remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the Journal of Herpetology -- see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Authors are urged to write the editors before submitting feature-length articles. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles are desired. Submissions should be black-and-white, 8 X 10, glossy prints, and should be accompanied by a descriptive caption and exposure data. The name and address of the contributor should be taped or penciled on the back of each print. Please DO NOT send photographs before corresponding with the editors about them. Return of unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions can be supplied if desired. Contributors will receive ordering information prior to publication of their material. Herpetological Review will accept commercial advertising. Rates and copy information are available from the editors.

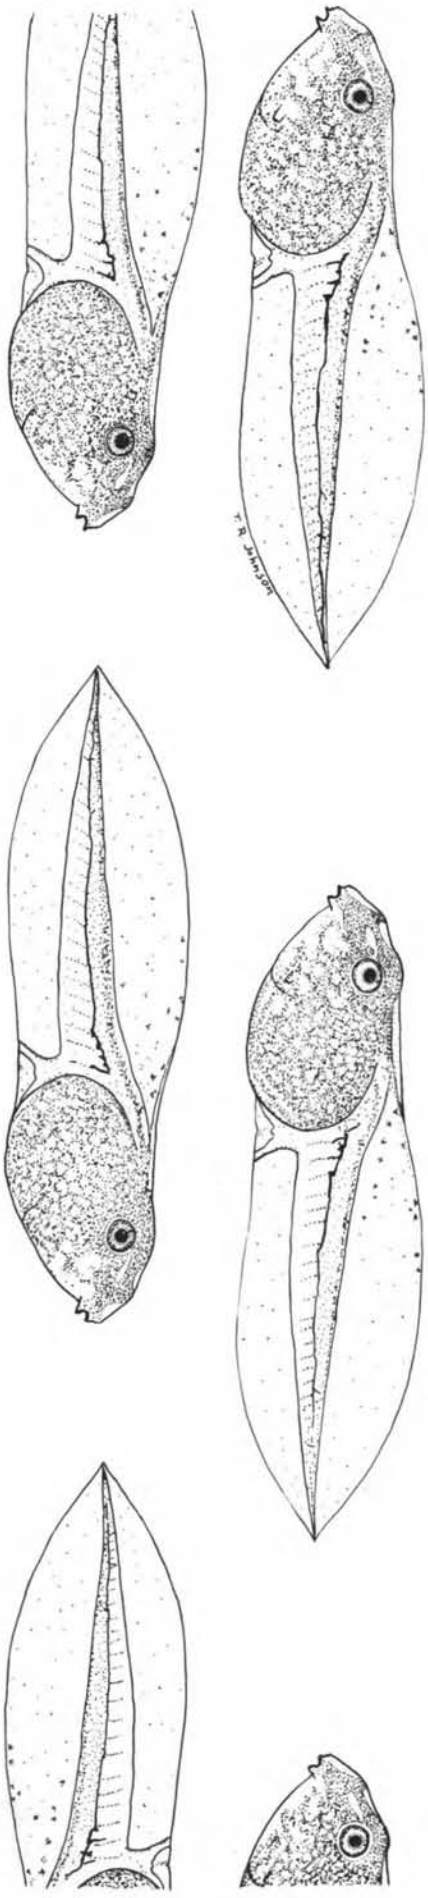
SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the Journal of Herpetology (four issues per year), Herpetological Review (four issues per year), Herpetological Circulars, and several Facsimile Reprints in Herpetology. Members may purchase other Society publications at reduced rates.

ANNUAL DUES



Student member	$10.00
Regular member	$12.00
Sustaining member	$20.00
Contributing member . . .	$25.00
Institutional	$20.00

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of the SSAR. For information about SSAR membership, write to:

Contents

SSAR ANNUAL MEETING NEWS
Titles of papers presented at the SSAR annual meeting at Arizona State University, Tempe 82
FEATURE ARTICLES
Herpetology on the Lewis and Clark Expedition 1804-1806, by K. R. Benson 87
A technique for the collection of serological and chromosomal material from small reptiles, by W. R. Branch 91
Two black rat snakes from one egg, by B. Schuette 92
Notes on three species of Micrurus (Serpentes: Elapidae) from Mexico, by R. M. Blaney and P. K. Blaney 92
Observations on an audio-visual "warning" signal in the pigmy rattlesnake, Sistrurus miliarius (Reptilia, Serpentes, Crotalidae), by A. Marchisin 92
The status of suppressed names and of Callopsis Gray (Reptilia: Testudines), by H. M. Smith 93
Feral dog predation of the gopher tortoise, Gopherus polyphemus (Reptilia, Testudines, Testudinidae) in southeast Alabama, by M. K. Causey and C. A. Cude . . 94
HERPETOLOGICAL HUSBANDRY
Photoperiod and reptile reproduction, by J. P. Jones 95
Observations on the reproduction of the emerald tree boa, Corallus caninus, by J. D. Groves 100
BOOK REVIEWS
"To Catch a Crocodile: Hunting in Papua/New Guinea" by Peter Pinney. Reviewed by J. Behler 102
"Amphibians and Reptiles in Alaska, The Yukon and Northwest Territories" by Robert Parker Hodge. Reviewed by M. M. Stewart 102

SSAR Annual Meeting News

Titles of Papers Presented at the SSAR Annual Meeting at Arizona State University, Tempe

Listed below are titles of herpetological papers presented at the 21st Annual Meeting of the Society for the Study of Amphibians and Reptiles held at Arizona State University, Tempe, in conjunction with the annual meetings of the American Society of Ichthyologists and Herpetologists and the Herpetologists' League. Also included are the name and address (as available) of the individual presenting the paper. SSAR members wishing a copy of an abstract should contact the author. Papers presented by title only are not listed.

ADEST, GARY
The relations of the sand lizards Uma, Callisaurus, Cophosaurus, and Holbrookia: an electrophoretic study. University of California, Los Angeles.

BACON, JAMES P.
Captive management of Geochelone elephantopus. San Diego Zoo.

BADER, ROBERT N.
Introduced amphibians and reptiles in south Florida and their effects on some native species. Brookneal, Virginia.

BAGNARA, JOSEPH T.
The Mexican leaf frog in captivity. University of Arizona, Tucson.

BEATTY, JOSEPH J.
Morphological variation in the clouded salamander, Aneides ferreus. Oregon State University.

BEHLER, JOHN L.
Breeding crocodilians in captivity: the current state of the art. Department of Herpetology, New York Zoological Society, Bronx, New York.

BENNETT, ALBERT F.
Speed and work capacity in small lizards. Biological Sciences, University of California, Irvine.

BERRY, JAMES F.
Distribution and phenetic relationships in Central American and Mexican Kinosternon scorpioides (Reptilia: Testudines: Kinosternidae). Dept. of Biology, University of Utah, Salt Lake City.

BERRY, KRISTIN H.
A preliminary report on the status of the desert tortoise in California. California Desert Program, Bureau of Land Management.

BIELITZKI, JOSEPH T.
The nutrition of captive reptiles. University of Washington.

BINKOWSKI, FRED P.
The routine and diurnal fluctuation in metabolism of the Ozark hellbender, Cryptobranchus alleganiensis bishopi. Zoology Department, University of Wisconsin-Milwaukee.

BIZER, JOHN R.
Growth rates and sizes at metamorphosis within and among populations of the tiger salamander. Rocky Mountain Biological Laboratory.

BLANEY, RICHARD M.
Taxonomic consideration of individual variation--a commentary. West Virginia State College.

BLOOM, CHARLES H.
Principal components analysis of the thermal niche of Hemidactylus turcicus turcicus. Baylor University.

BOHLIN, RAYMOND G.
Thermal exchange times of the aquatic salamander, Amphiuma means. North Texas State University.

BOWLER, J. KEVIN
Modern management and exhibit techniques for reptiles. Philadelphia Zoo.

BRAMBLE, DENNIS M.
Functional and evolutionary correlates of burrowing behavior in gopher tortoises. Dept. of Biology, University of Utah, Salt Lake City.

BRODE, JOHN M.
Protection of amphibians and reptiles in Californa. California Department of Fish and Game.

BROOKS, GARNETT R.
Methods for estimating home range size in lizards: an evaluation. College of William and Mary.

BROWN, WESLEY M.
The origin and relative age of parthenogenetic lizards (Genus Cnemidophorus) as determined by mitochondrial DNA analyses. University of California, San Francisco.

BRUCE, RICHARD C.
Metamorphosis and life-cycle partitioning in the salamander Gyrinophilus porphyriticus. Western Carolina University.

BURY, R. BRUCE
UMA to UMA. National Fish and Wildlife Laboratory.

BUSH, MITCHELL
Antibiotic studies in snakes and turtles. National Zoological Park, Washington, D.C.

BUTLER, JOSEPH A.
A comparison of heating and cooling rates of summer-acclimated and spring-acclimated queen snakes, Regina septemvittata (Say). Ohio State University.

CADLE, JOHN
Genetic differentiation in the plethodontid salamander Aneides ferreus. University of California, Berkeley.

CANNATELLA, DAVID
A systematic re-assessment of phyllomedusine frogs. University of Kansas, Lawrence.

CARPENTER, CHARLES C.
An ethological approach to reproductive success in reptiles. Univeristy of Oklahoma, Norman.

CHRISTMAN, STEVEN P.
Successful changes in community structure: amphibians and reptiles in Florida Sand Pine Scrub. National Fish and Wildlife Laboratory, Gainesville, Florida.

COLLINS, JAMES P.
The selective advantage of neoteny in salamanders. Arizona State University, Tempe.

COLLINS, JOSEPH T.
Summary of the symposium of reproductive biology of captive reptiles. University of Kansas, Lawrence.

CONANT, ROGER
Introduction and historical perspectives. University of New Mexico, Albuquerque.

COWAN, DANIEL F.
Adaptation, maladaptation and disease. University of Texas, Houston.

CREWS, DAVID
Methods for inducing reproduction in captive reptiles. Harvard University.

DAUGHERTY, CHARLES H.
Evolution and systematics of the genus Dicamptodon. Department of Zoology, University of Montana, Missoula.

DEAKINS, DENNIS E.
Helminth diagnosis and treatment in captive reptiles. Scott and White Hospital.

DERICKSON. W. KENNETH
Resource availability and reptilian life history strategies. Biotic considerations. Argonne National Laboratory.

DEWEESE, JAMES E.
Chromosomal load in the leptodactylid frog genus, Eleutherodactylus. University of Southern California.

DIAL, BENJAMIN E.
Physiological and ecological correlates in sympatric Coleonyx. North Texas State University.

DOLENSEK, E. P.
Reptilian anesthesia. New York Zoo.

DUNHAM, ARTHUR E.
Proximal sources of variation in age-specific fecundity, individual growth rates, and levels of stored lipids in two iguanid lizards. University of Michigan, Ann Arbor.

DUNSON, WILLIAM A.
A new salt gland in a marine homalopsid snake. Pennsylvania State University, State College.

DUVALL, DAVID
Chemical-signal release of display action-patterns and mediation of a conspecific odor preference in western fence lizards (Sceloporus occidentalis). University of Colorado, Boulder.

DUVALL, DAVID
Stimulation of land-drive in recently transformed tiger salamanders (Ambystoma tigrinum) by endogenous or exogenous thyroxine. University of Colorado, Boulder.

EAGLESON, GERALD W.
Histological studies of larval, metamorphosing, neotenic, and transformed Ambystoma gracile. University of Texas, Austin.

EHRENFELD, DAVID W.
Commercial breeding in captive sea turtles: status and prospects. Rutgers University.

ELIAS, PAUL
Biogeography of the plethodontid salamanders of Nuclear Central America. University of California, Berkeley.

EMERSON, SHARON B.
The ilio-sacral articulation in frogs: form and function. University of Illinois at Chicago Circle.

ERSKINE, DALE J.
A computer simulation of closed-system respirometry with small ectotherms. Dept. of Zoology, University of Oklahoma, Norman.

FELLERS, GARY M.
The breeding behavior of Hyla versicolor and Hyla crucifer. Department of Biological Sciences, California State University, Sacramento.

FERGUSON, GARY W.
Differences in growth of two species of Sceloporus in similar laboratory environments. Texas Christian University.

FITCH, HENRY S.
Reproductive strategies of reptiles. University of Kansas, Lawrence.

FITZGERALD, KEVIN T.
Mate selection as a function of body size. University of Colorado, Boulder.

FORD, NEIL B.
Orientation to pheromone trails in thamnophiine snakes. Miami University, Oxford, Ohio.

FOWLER, MURRAY E.
A summary and some differential diagnostic concepts applicable to reptiles. University of California, Davis.

FROST, J. S.
Interspecific reproduction isolation of Arizona leopard frogs. University of Arizona, Tucson.

FROST, SALLY K.
The dual function of xanthine dehydrogenase during Mexican leaf frog (Pachymedusa dacnicolor) development and metamorphosis. University of Arizona, Tucson.

GATTEN, JR., ROBERT E.
Aquatic oxygen uptake in snapping turtles (Chelydra serpentina). Dept. of Biology, Univ. of Toledo, Ohio.

GILLINGHAM, JAMES C.
Analysis of combat behavior in the rat snake, Elaphe obsoleta. Central Michigan University.

GLIDEWELL, J. R.
Metabolic compensation to seasonal temperatures in the red-eared turtle, Chrysemys scripta. North Texas State University.

GODLEY, J. STEVE
Feeding behavior and handling time in newborn striped swamp snakes, Regina alleni. University of South Florida, Tampa.

GOLDBERG, STEPHEN R.
Reproduction in two Namib Desert lacertid lizards (Aporosaura anchietae and Meroles cuneirostris). Whittier College.

GONG, JULIANN D.-U.
Histological changes in the urogenital organs and interrenal tissue of the male lizard Anolis carolinensis following estradiol treatments. University of Nebraska, Omaha.

GREEN, DAVID M.
Morphological and functional characters of treefrog digital pads using scanning electron microscopy. University of Guelph, Canada.

GREENE, HARRY W.
Skinks, snakes, and the predator-prey race. University of Pennsylvania.

GREGORY, PATRICK T.
Temperature relationships of garter snakes on Vancouver Island. University of Victoria, British Columbia.

HALL, RUSSELL J.
Effects of selected pesticides on larval and adult amphibians. Patuxent Wildlife Research Center, Laurel, Maryland.

HAMMERSON, GEOFFREY A.
The applicability of the "Preferred body temperature" concept to snakes: examples from the genus Masticophis. California State University, Hayward.

HANKEN, JAMES
Genetic diversification within the salamander genus Thorius. Museum of Vertebrate Zoology, University of California, Berkeley.

HARLAN, RICHARD A.
The effects of dissolved oxygen content of water on blood pH, pCO2, p(w) and rocking activity for Cryptobranchus alleganiensis. Southwest Missouri State University.

HARRISON, JULIAN R.
Preliminary observations on the status and distribution of two color pattern morphs in South Carolina populations of Eurycea quadridigitata (Holbrook). The College of Charleston.

HAZARD, E. STARR
Ontogenetic changes in erythrocytic phosphates in the bullfrog, Rana catesbeiana. Dept. Zoology, Univ. Oklahoma, Norman.

HEBRARD, JAMES J.
Annual variations in resource partitioning among four syntopic

Nerodia. Louisiana State University.

HENDRICKSON, J. R.
Evidence for population discrimination in marine turtles by amino acid analysis of shell keratin. University of Arizona, Tucson.

HERRON, M. R.
Surgery and radiography of reptiles. Texas A & M University, College Station.

HIGHTON, RICHARD
The genetic relationships of the woodland salamanders of the genus Plethodon. University of Maryland, College Park.

HOWARD, RICHARD D.
Mating systems of bullfrogs and woodfrogs. Bowling Green State University.

HUEY, RAYMOND B.
Zoogeographical, ecological, and reproductive consequences of altitude in amphibians and reptiles from western North America. University of Washington.

HUFF, THOMAS A.
Captive propagation of the boinae, with particular emphasis on the genus Epicrates. Reptile Breeding Foundation, Pickton, Ontario.

HUGHES, ANDY
Erythrocytic organic phosphates: diel cycle in the diamondback water snake, Nerodia rhombifera. Dept. of Zoology, Univ. of Oklahoma, Norman.

HUNT, R. HOWARD
Propagation of the Morelet's crocodile, Crocodylus moreleti, for restocking. Atlanta Zoo, Georgia.

HUNTLY, ANTHONY C.
Sleep in the western toad, Bufo boreas. California State University, Fullerton.

HUTCHISON, VICTOR H.
Erythrocytic organic phosphates: diel and seasonal cycles in the frog Rana berlandieri. University of Oklahoma, Norman.

IVERSON, JOHN B.
Colic modification and the herbivory-body size correlation in lizards. University of Florida, Gainesville.

JACKSON, DALE R.
Effects of severe drought on the herpetofauna (and ichthyofauna) of a Florida marsh. University of Florida, Gainesville.

JACOB, JAMES S.
The heart rate-ventilatory response in terrestrial snakes. Memphis State University, Tennessee.

JACOBSON, ELLIOTT
Viral diseases of reptiles. University of Florida, Gainesville.

JACOBSON, ELLIOTT
Mycotic diseases of reptiles. University of Florida, Gainesville.

JACOBSON, ELLIOTT
Neoplastic diseases of reptiles. University of Florida, Gainesville.

JAEGER, ROBERT G.
Foraging tactics of the salamander Plethodon cinereus. State University of New York, Albany.

JENKINS, JAMES D.
Preferred defecation sites in the banded gecko Coleonyx variegatus. Arizona State University, Tempe.

JENSSEN, THOMAS A.
Vocalizations by an iguanid lizard, Anolis grahami. Virginia Polytechnic Institute and State University.

JOANEN, TED
Reproductive biology of the American alligator. Louisiana Department of Wildlife and Fisheries, Grand Chenier.

JOHN, KENNETH R.
Periphery versus volume of container in growth of crowded tadpoles. Franklin and Marshall College.

JOHNSON, JAMES E.
Developing critical habitat for the Houston toad (Bufo houstonensis). U.S. Fish and Wildlife Service, Albuquerque.

JUTERBOCK, J. ERIC
Evolutionary implications of variation in desmognathine jaw tooth morphology. Ohio State University, Columbus.

KAPLAN, ROBERT H.
Size and shape as constraints on reproduction in salamanders. Brooklyn College, New York.

KARLIN, ALVAN A.
Natural hybridization between Desmognathus fuscus and D. ochrophaeus (Plethodontidae) in northern Ohio. Miami University, Oxford, Ohio.

KARLSTROM, ERNEST L.
Contributions to northwest herpetology: a historical review. University of Puget Sound.

KEEFER, TOM
Niche compression in two nocturnal lizards, and observations of intraspecific social behavior in a sphaerodactyline gecko. Austin, Texas.

KLEESE, WILLIAM C.
Environmental effects upon herpesvirus infections in sea turtles. University of Arizona, Tucson.

KLUGE, ARNOLD G.
Sexual selection, territoriality and the evolution of parental care in Hyla rosenbergi. Museum of Zoology, University of Michigan, Ann Arbor.

LABANICK, GEORGE M.
An experimental study of batesian mimicry between red-legged morphs of the salamanders Plethodon jordani and Desmognathus ochrophaeus. Southern Illinois University, Carbondale.

LAPOINTE, JOE
Activity cycles and thermoregulation in Xantusia (Klauberina) riversiana). New Mexico State University.

LEUCK, BETH E.
Shell variation in a population of three-toed box turtles (Terrapene carolina triunguis). University of Oklahoma, Norman.

LOMBARD, R. E.
Underwater hearing in frogs. University of Chicago.

LOOMIS, RICHARD B.
Ectoparasites of captive reptiles. California State University, Long Beach.

LUCKENBACH, ROGER A.
Lizard species diversity in aeolian sand habitats. University of California, Berkeley.

LYNCH, JAMES F.
Patterns of ontogenetic and geographic variation in the black salamander (Aneides flavipunctatus). Smithsonian Institution, Washington, D.C.

MANNES, JOSEPH D.
Heat hardening in amphibians. University of Oklahoma, Norman.

MANNES, S. J.
Thermal biology of Podocnemis vogli in the Venezuelan llanos. California State College, Sonoma.

MARCHISIN, ALLEN
Predator-prey relationships between pit vipers (Reptilia, Serpentes, Viperidae) and the ophiophagous snakes Lampropeltis getulus getulus and Drymarchon corais couperi (Reptilia, Serpentes, Colubridae).

MARCUS, LEONARD C.
Bacterial infections of reptiles. Massachusetts State Laboratory Institute.

MARLOW, RONALD WILLIAM
Energy relations in the desert

tortoise, Gopherus agassizi. University of California, Berkeley.

MAUTZA, WILLIAM J.
Metabolic and thermal correlates of reclusive behavior in xantusiid lizards. Cornell University, Ithaca, New York.

MAXSON, L. R.
Evolution in the salamander genus Plethodon: phylogenetic implications of MC'F studies of albumins. University of Illinois, Urbana.

MCDIARMID, ROY W.
Evolutionary and ecological consequences of reproductive behavior in centrolenid frogs. University of South Florida, Tampa.

MCGILLIS, SAMUEL M.
Thermoregulation in the green sea turtle, Chelonia mydas. California State University, Hayward.

MEANS, D. BRUCE

Herpetology on the Lewis and Clark Expedition 1804-1806

One of the main goals of the overland exploration to the new Northwest territory, commissioned by Thomas Jefferson and led by Meriwether Lewis and William Clark between 1804-1806, was to compile a comprehensive list of the flora and fauna of the Northwest region. As a result, the journals Lewis and Clark kept during their journey to the Northwest contain a wealth of information concerning the natural history of the area. Typical of the thrust in natural history during the early part of the nineteenth century, their journal accounts reflect an overwhelming preoccupation with ornithology, botany and mammalogy. Mammals received particular attention because of their importance both as a food source for the naturalists and for the economic value of their fur. The herpetological forms of this area are given little treatment in the journals. Most references to reptiles and amphibians are of an incidental nature and, therefore, appear to be subsidiary information to the main body of knowledge compiled by the expedition. In spite of the "second billing" status of herpetology on the overland exploration, much information can be obtained concerning these animals by a careful examination of the journal passages in which references are made to reptiles and amphibians.

Unfortunately, there has been little attention paid to the herpetological observations of Lewis and Clark. In fact, until fairly recently there have been few attempts to examine any of the natural history done on the expedition. Most of this neglect can be attributed to the tendency of treating Lewis and Clark as pioneering explorers, adventurous woodsmen and able military leaders. The Natural History of Lewis and Clark Expedition (Burroughs, 1961) and Lewis and Clark: Pioneering Naturalists (Cutright, 1969) have been two recent attempts directed toward providing an additional interpretation of the overland explorers. Both authors attempt to depict Lewis and Clark as able amateur naturalists by emphasizing the zoological aspects of the expedition. In this attempt, Burroughs and Cutright have set out to characterize the animal forms described by the two naturalists in their journals. Generally, the classifications have been enormously successful. However, complete satisfaction is lacking in reference to the classification and description of the herpetological forms.

There are several conjectural reasons to explain the unsatisfactory treatment of the reptiles and amphibians. First, many of the references Lewis and Clark made to these animals are very scanty and descriptively superficial. This fact alone has made exact identification of species difficult in many cases and almost impossible in a few instances. Secondly, neither Burroughs nor Cutright appear to have placed the necessary emphasis upon a careful scrutiny of the herpetological entries in the journals. It is not apparent that either author consulted a herpetologist to aid in these descriptions. Burroughs did not list any reference to herpetological guides, check lists or manuals in his bibliography. Cutright utilized only three herpetology references (Cope, 1900; Stejneger and Barbour, 1939; Schmidt, 1953). Two of these are quite old and none emphasizes western species. Thirdly, neither author appears to have an extensive personal acquaintance with the reptiles and amphibians of the Northwest. As a result, their identifications of species described by Lewis and Clark often rely upon reference to dominant species usually found in a given geographical area. In several cases, such a technique has resulted in erroneous identification.

The procedure followed in this study has been to refer to the journals of the expedition (Thwaites, 1904-05) to examine the field descriptions Lewis and Clark have provided concerning the animal they examined, and to consult, when necessary, herpetological field guides and maps to provide an accurate identity to the species under consideration (Stebbins, 1966). In several cases, the result of this study has been to correct previously erroneous identifications. Additionally, it has allowed identification of species not previously identified. However, there are a few instances in which several possible species are provided instead of the one species usually described. In these cases, the problem is one of narrowing the possible species down to the most likely species; that is, the descriptions offered in the journals do not allow for a more precise identification.

SALAMANDERS

1. Taricha granulosa, rough-skinned newt

William Clark, Fort Clatsop, Oregon, March 12, 1806.

"There is a species of water lizard of which I only saw one just above the grand rapid of the Columbia. it is about 9 inches long the body is reather flat and about the size of a mans finger, covered with a soft skin of dark brown colour with an uneven surface covered with little pimples, the neck and head are short, the latter terminating in an accute angular point and flat, the fore feet each have four toes, the hinder ones five unconnected with a web and destitute of tallons. it's tail was reather longer than the body, and in the form like that of the Muskrat, first riseing in an arch higher than the back, and descending lower than the body at the extremety, and flated perpendicularly. the belley and under part of the neck and head were of a Brick red every other part of the colour of the upper part of the body are dark brown the mouth was smooth without teeth." (Thwaites, Vol. IV, p. 162.)

The skin texture, coloration and general body description along with the habitat indicates that Clark was describing Taricha granulosa. While the venter is not characteristically "Brick red," specimens have been observed with a reddish orange color on the ventral surface (Stebbins, 1966). Clark noted that the "water lizzard" did not have teeth, but perhaps this incorrect observation was the result of a brief visual examination. If he had felt the roof of the mouth of Taricha, he would have noticed that the newt does have teeth, although they are not readily visible. The most convincing evidence for this identification, however, comes from the distribution of Taricha. It is the only newt or salamander found in the Columbia River region even closely resembling Clark's description.

Burroughs (1961, p. 280) erroneously identifies this newt as Diemyctylus torosus, the California newt. D. torosus is indigenous to California, not Oregon (Stebbins, 1966). Cutright (1969, p. 429) makes the same error as Burroughs. He also adds the incorrect species names of Tritorus torosus torosus and Triton torosus.

FROGS

2. Bufo boreas, western toad

Meriwether Lewis, Kamiah, Idaho, May 30, 1806.

"a large species of frog which resorts the water considerably larger than our bull frog, it's shape seems to be a medium between the delicate and lengthy form of our bull frog and that of our land frog or toad as they are sometimes called in the U'States. like the latter

their bodies are covered with little pustles or lumps, elivated above the ordinary surface of the body; I never heard them make any sound or noise." (Thwaites, Vol. V, p. 87).

Lewis's description is probably of a Bufo, and the only large Bufo frequenting this part of Idaho is Bufo boreas. While Lewis claimed to have never heard the toad call, western Bufo boreas does have a mellow chirping. However, the voice is not remarkable as B. boreas does not have a resonating vocal pouch (Stebbins, 1954). In addition, Bufo boreas is one of the anurans losing its species specific mating call. The toad is found in regions where no other similar species occurs and, consequently, little or no opportunities for cross-mating exist (Porter, 1972). Habitat and range characteristics of the frog from the journals are also consistent with current descriptions of Bufo boreas. The toad prefers water or moist habitats and is widely distributed throughout the Northwest, Idaho, Montana and Wyoming.

3. Hyla regilla, Pacific tree frog

4. Pseudacris triseriata, chorus frog

Meriwether Lewis, Yellowstone (Wyoming-Montana region), April 15, 1805.

"I heard the frogs crying for the first time this season; their note was the same with that of the small frogs which are common to the lagoons and swamps of the U. States." (Thwaites, Vol. I, p. 312)

Meriwether Lewis, Fort Clatsop, Oregon, March 29, 1806.

"The frogs are croaking in the swamps and marshes; their notes do not differ from those of the Atlantic States." (Thwaites, Vol. IV, p. 216.)

Meriwether Lewis, Fort Clatsop, Oregon, March 30, 1806.

"The frogs are now abundant and are crying in the swamps and marshes." (Thwaites, Vol. VI, p. 211.)

Meriwether Lewis, Kamiah, Idaho, May 30, 1806.

"a smal green tree-frog." (Thwaites, Vol. V, p. 87.)

The description, "a smal green tree-frog," definitely refers to Hyla regilla. It is a widespread species in the Northwest and is the species responsible for most of the calls and "crying in the swamps and marshes." However, the range of Hyla does not extend into the Yellowstone region. While Lewis did not mention actually observing the frog, he did note its voice similarity to the small frogs of the United States. My supposition is that Lewis may have been referring to the boreal chorus frog, Pseudacris triseriata, which is dispersed widely from the Rocky Mountains to the Eastern seaboard.

Cutright (1969, p. 428) refers to the frog in the Lower Columbia region between the Lewis River and Fort Clatsop as Rana pretiosa. This identification is highly unlikely. While the range of R. pretiosa may have been markedly reduced in the last 150 years by Rana catesbeiana, it probably had a very limited distribution west of the Cascades. When found in this area, it is usually limited to cold, fast waters. In addition, the voice of R. pretiosa is unknown (Stebbins, 1966). The journal entries made definite reference to the calls of the frog.

TURTLES

5. Trionyx spiniferus hartwegi, western spiny softshell turtle.

Meriwether Lewis, Musselshell River on eastern slope of Rocky Mountains, May 26, 1805.

"near it's entrance it had a handsome little stream of running water; in this creek I saw several softshelled Turtles which were the first that had been seen this season;" (Thwaites, Vol. II, p. 79).

William Clark, Musselshell River on eastern slope of Rocky Mountains, May 26, 1805.

"we passed 2 creeks on the Stard Side both of them had running water in one of those Creek Capt Lewis tells me he saw soft shell Turtle." (Thwaites, Vol. II, p. 83.)

William Clark, Tongue River in Yellowstone area, July 29, 1806.

"The river widens I think it may be generally Calculated at from 500 yards to half a mile in width more Sand and gravelly bars than above. cought 3 catfish. They were small and fat. also a Soft Shell turtle." (Thwaites, Vol. V, p. 307.)

There is only one softshell turtle which has a range into the Yellowstone region, Trionyx spiniferus hartwegi. Cutright (1969, p. 337) provides an incorrect name for this turtle, Amyda spinifera spinifera.

6. Chrysemys picta, painted turtle.

Meriwether Lewis, Great Falls, Montana, June 25, 1805.

"see a number of water terrapins." (Thwaites, Vol. II, p. 186.)

From this extremely abbreviated reference, positive identification of the turtle species is impossible. However, a conjectural identification based upon the range of specific turtles can be offered. Chrysemys picta is widely distributed in the Rocky Mountain region and is quite common in Montana.

Cutright (1969, p. 428) describes the turtle as Pseudemys troosti elegans or Emys elegans. The accepted name for this turtle is Chrysemys scripta elegans (Conant, 1975), but even this name is incorrect since this species had a more southern dispersal.

LIZARDS

7-8. Phrynosoma douglassi, pigmy horned lizard (P. d. douglassi) and Eastern short-horned lizard (P. d. brevirostre).

Meriwether Lewis, Upper Kooskooske between Walla Walla and the Bitter Root Mountains, May 29, 1806.

"a species of lizzard called by the French engages prairie buffaloe are native of these plains as well as those of the Missouri. I have called them the horned lizzard. They are about the size and a good deal of the figure of the common black lizzard. but their bellies are broader, the tail shorter and their action much slower; they crawl much like the toad. they are of a brown colour. arround the edge of the belley is regularly set with little horney projections which give to these edges a serrate figure the eye is small and of a dark colour. above and behind the eyes there are several projections of the bone which being armed at their extremities with a firm black substance has the appearance of horns sprouting out from the head. this part has induced me to distinguish it by the appellation of the horned Lizzard. I cannot conceive how the engages ever assimilated this animal with the buffaloe for there is not greater analogy than between the horse and the frog. this animal is found in greatest numbers in the sandy open parts of the plains, and appear in great abbundance after a shower of rain; they are sometimes found basking in the sunshine but conceal themselves in little holes in the earth much the greater proportion of their time. they are numerous about the falls of the Missouri and in the plains through which we past lately above the Wallahwallahs." (Thwaites, Vol. V, pgs. 80-81.)

Both Lewis and Clark made several other entries in the journals to the horned toad or "horned Lizzard." This species is so distinct that it is unquestionably Phrynosoma douglassi, the only species of horned lizard found in this area. There are two subspecies the naturalists probably encountered. In the Columbia River region, P. d. douglassi is commonly found, while the subspecies P. d. brevirostre is the horned toad observed in Montana, Wyoming and the Dakotas.

Cutright (1969, p. 428) incorrectly describes the horned lizard as Phrynosoma cornutum. The error can be attributed to lack of attention to range maps. P. cornutum is the species native to Texas, Oklahoma, New Mexico and northern Mexico. The northern species is P. doug-

lassi, which ranges from Oregon to the Dakotas.

9. Sceloporus occidentalis, Western fence lizard.

Meriwether Lewis, Fort Clatsop, Oregon, March 11, 1806.

"the black or dark brown Lizzard we saw at the rock fort Camp at the commencement of the woody country below the great narrows and falls of the Columbia; they are also the same with those of the United States." (Thwaites, Vol. IV, p. 155.)

There are numerous references of a casual nature referring to the "common Lizzard" or the black or "dark brown Lizzard." The problem with providing an accurate identification of these lizards is that there is not a species of lizard so ubiquitous in the United States to fit uniformly the widespread distribution to which Lewis refers. However, if we look back to Lewis' description of P. douglassi, there is a relative description of the "common black lizard." This lizard is about the same size and shape of the horned toad, but the abdomen is narrower, the tail longer and the action of the lizard is much more rapid. The general body description, shape and the habits of the lizard correspond to Sceloporus occidentalis, a species found throughout Oregon and a member of a genus which is spread across the United States. The only problem with this identification is that S. occidentalis has a brilliant blue to turquoise coloration on the belly. If Lewis had carefully examined this lizard, he should have been sufficiently impressed by the coloration to make note of it in the journals. Perhaps he did notice the coloring, but failed to make permanent record of it. Or, perhaps he could not capture the elusive lizard and did not notice the ventral coloring, or caught only dull-colored females or young. As previously mentioned, his lack of careful attention to detail in regard to the lizards can be explained by the general lack of interest in the collection of herpetological forms. From the sketchy descriptions of salamanders, turtles and frogs, it should be apparent that there was not much emphasis upon making a careful record of reptilian or amphibian detail.

The only other possible lizards that Lewis could have observed would have been Eumeces skiltonianus, Gerrhonotus coeruleus and Gerrhonotus multicarinatus. Again, E. skiltonianus is a brownish lizard with very rapid motion, but the body is very slender and in no way is similar to the horned toad. Additionally, this lizard usually has a bright blue tail, a fact sure to attract even the most casual observer. Both Gerrhonotus species could have been sighted, but Lewis's reference appears to be much more consistent with Sceloporus occidentalis. It is also quite probable that the naturalists could have lumped all sightings of lizards under the rubric of "common Lizzard."

SNAKES

10. Opheodrys vernalis, smooth green snake.

William Clark, Salt River, Missouri, September 19, 1806.

"saw a green Snake as high up as Salt Rivr on the Missouri." (Thwaites, Vol. VI, p. 229.)

From the distribution of green snakes, the only species Clark could have been describing is the smooth green snake, Opheodrys vernalis. It is the only snake with this coloration that inhabits the Missouri region. In addition, isolated populations are located in the mountains in the southern and western part of its range, which includes the Dakotas, Missouri, Wyoming, Montana and Idaho.

11-12. Pituophis melanoleucus, bullsnake or gopher snake.

Meriwether Lewis, Blair, Nebraska, August 5, 1804

"Killed a serpent on the bank of the river adjoining a large prairie

Length from nose to tail, 5F 2 Inch

Circumpherence in largest part, 4 1/2

Number of scutta on belly, 221

Dd. on Tale, 53

No pison teeth therefore think him perfectly inocent, eyes, center black with a border of pale brown yellow Colour of skin on yead yellowish green with black specks on the extremity of the scuta which are pointed or triangular colour of back, transverse stripes of black and dark brown of an inch in width, the end of the tale hard and pointed like a cock's spur the sides are speckled with yellowish brown and black. two roes of black spots on lite yellow ground pass throughout his whole length on the upper points of the scuta of the belly and tale 1/2 Inch apart this snake is vulgarly called the cow or bull snake from a bellowing nois which it is said sometimes to make resembling that animal tho' as to this fact I am unable to attest it myself." (Thwaites, Vol. VI, p. 124.)

Sergeant Charles Floyd, Blair, Nebraska, August 5, 1804.

"a verry large Snake was Killed to day Called the Bull Snake his Colure Something like a Rattel Snake..." (Thwaites, Vol. VI, p. 24.)

Meriwether Lewis, Bonhamme County, South Dakota, September 5, 1804.

"This day one of our hunters brought us a Serpent beautifully variegated with small black spotts of a romboydal form on a light yellow white ground. the black predominate most of the back the whiteish yellow on the sides, and it is nearly white on the belly with a few partly couloured scuta in which the black shews but imperfectly and the colouring matter seems to be underneath the Scuta, it is not poisonous it hisses remarkably loud; it has 221 Scuta on the belly and 51 on the Tale, the eyes are of a dark black colour the tale terminates in a sharp point like the substance of a cock's spur. Length 4F 6I." (Thwaites, Vol. VI, p. 128.)

Meriwether Lewis, Upper Kooskoose, Idaho, May 16, 1806.

"I killed a snake near our camp, it is 3 feet 11 Inches in Length, is much the colour of the rattlesnake common to the middle atlantic states, it has no poisonous teeth. it has 218 scutae on the abdomen and fifty nine squmae or half formed scutae on the tail. the eye is of moderate size, the iris of a dark yellowish brown and purple black. there is nothing remarkable in the form of the head which is not so wide across the jaws as those of the poisonous clas of snakes usually are. I preserved the skin of this snake." (Thwaites, Vol. V, p. 42.)

William Clark, Upper Kooskooske, Idaho, May 16, 1806.

"a snake which resembles the rattle snake in colour and spots on the skin, larger and inosent." (Thwaites, Vol. V, p. 43.)

The descriptions given above are undoubtedly of Pituophis melanoleucus, the bullsnake or gopher snake. It is an ubiquitous species of snake in the West, especially appearing in the grasslands and open brushlands, extending as far east as the Mississippi Valley. Because of its coloration, it is often mistaken for the rattlesnake, a fact Lewis mentioned in several places. Perhaps this accounts for his careful inspection of the snake for poisonous teeth.

There are two subspecies of P. melanoleucus that Lewis and Clark encountered. Those gopher snakes described from the Montana, Wyoming and Dakota region were P. m. sayi (bullsnake); those in Idaho and Oregon were P. m. deserticola (Great Basin gopher snake). While there are no direct references to the gopher snake in western Oregon, the subspecies in this area is P. m. catenifer (Pacific gopher snake).

13. Thamnophis elegans vagrans, wandering garter snake.

Meriwether Lewis, Three Forks, Montana, July 24, 1805.

"we observed a great number of snakes about the water...speckled on the bottom and striped with black and brownish yellow on the back and sides...much like the garter snake of our country and about its size ...they all appear to be fond of the water." (Thwaites, Vol. II, p. 266.)

From the description Lewis offered concerning the coloration and habitat and from the location of this snake near Three Forks, Montana, this species can most accurately be identified as Thamnophis elegans vagrans. Distinguishing characteristics include the speckling on the venter and the prominent mid-dorsal stripe extending the length of the body accompanied by lateral striping. In addition, a common trait of the wandering garter snake is to enter water, if it is available, when frightened. This behavior could account for Lewis's observation that the snakes "appear to be fond of the water."

Cutright (1969, p. 429) identifies this snake as Thamnophis ordinoides. While Lewis and Clark probably observed T. ordinoides on some part of their exploration, they were not making reference to this snake in the journal entry from Montana. T. ordinoides is restricted to the Northwest coast.

14. Thamnophis sirtalis, common garter snake.

Meriwether Lewis, Deer Island in Columbia River, Oregon, March 28, 1806.

"we saw a great number of snakes on this island; they were about the size and much the form of the common garter snake of the Atlantic coast and like that snake are not poisonous. they have 160 scuta on the abdomen and 71 on the tail. the abdomen near the head, and jaws are high as the eyes, are of a bluish white, which as it recedes from the head becomes of a dark brown. the field of the back and sides is black. a narrow stripe of a light yellow runs along the center of the back, on each side of this stripe there is a range of small transverse oblong spots of a pale brick red which gradually diminish as they recede from the head and disappear at the commencement of the tail. the purple of the eye is black, with a narrow ring of white bordering it's edge; the ballance of the iris is of a dark yellowish brown." (Thwaites, Vol. IV, p. 211.)

Lewis's description of this snake is one of the most detailed observations conducted by any member of the expedition concerning reptiles. Without a doubt, his notes enable this snake to be positively identified as Thamnophis sirtalis (subspecies concinnus). The distinguishing characteristic of T. sirtalis is the "pale brick red" coloring on the side of the snake. Due to this coloration, the snake is commonly referred to as the red-sided garter snake.

15-16. Thamnophis spp., other garter snakes.

Meriwether Lewis, Sauvies Island in Columbia River, Oregon, March 29, 1806.

"the garter snakes are innumerable and are seen entwined arround each other in large bundles of forty or fifty lying about in different directions through the prairies." (Thwaites, Vol. IV, p. 214.)

From this and other passages referring to the prevalence of garter snakes, it is highly likely that two other species, Thamnophis elegans and Thamnophis ordinoides, were also sighted in the Oregon territory. Both species are widely distributed in western Oregon.

17. Crotalus viridis oreganus, Northern Pacific rattlesnake.

Meriwether Lewis, Arlington, Oregon, April 25, 1806.

"several rattlesnakes killed by the party, they are the same common to the U. States." (Thwaites, Vol. IV, p. 323.)

Meriwether Lewis, Walla Walla, Washington, May 30, 1806.

"The reptiles which I have observed in this quarter are the Rattlesnake of the species discribed on the Missouri. they are abundant in every part of the country and are the only poisonous snake which we have yet met with since we left St. Louis." (Thwaites, Vol. V, p. 86.)

Crotalus viridis oreganus is the subspecies of rattlesnake found in the Columbia River area of Oregon with the range stretching into the region where Oregon, Washington and Idaho meet. These two references represent two of the more extended journal entries regarding the rattlesnake. The journals contain many accounts of rattlesnake sightings, captures and kills.

18. Crotalus viridis viridis, prairie rattlesnake.

Meriwether Lewis, Yellowstone region (Montana-Wyoming), May 17, 1805.

"Capt. Clark narrowly escaped being bitten by a rattlesnake in the course of his walk...this snake is smaller than those common to the middle Atlantic States, bieng about 2 feet 6 inches long; it is of a yellowish brown colour on the back and sides, variegated with one row of oval spots of a brown colour lying transversely over the back from the neck to the tail, and two other rows of small circular spots of the same colour which garnish the sides along the edge of the scuta. it's bely contains 126 scuta on the belly and 17 on the tale." (Thwaites, Vol. II, p. 41-42.)

Meriwether Lewis, Maries River, Montana, June 15, 1805.

"when I awoke from my sleep today I found a large rattlesnake coiled on the leaning trunk of a tree under the shade of which I had been lying at a distance of about ten feet from him. I killed the snake and found that he had 176 scuta on the abdomen and 17 half formed scuta on the tale; it was of the same kinde which I had frequently seen before; they do not differ in their colours from the rattle-snake common to the middle atlantic states, but considerable in the form and figures of those colours."

Meriwether Lewis, Yellowstone region (Montana-Wyoming), August 4, 1806.

"during our halt we killed a very large rattlesnake of the speceis common to our country. it had 176 scutae on the abdomen and 25 on the tail, it's length 5 feet. the scutae on the tail half formed." (Thwaites, Vol. V, p. 234.)

The rattlesnakes mentioned in these selections have been identified from the locations that Lewis cited in his journals and from the present ranges of the subspecies. Crotalus viridis viridis frequents most of Montana and Wyoming.

Admittedly, while some of the species identifications made in this study have been conjectural or have been based upon fairly sketchy evidence from the journals, the intent in this account has been to re-examine the details provided by Lewis and Clark in an effort to give a more accurate description of the reptile and amphibian forms encountered by the two explorers than has heretofore been provided.

A Technique for the Collection of Serological and Chromosomal Material from Small Reptiles

In recent years, biochemical and chromosomal methods of taxonomic analysis have been employed with increasing frequency by herpetologists. The need for these additional criteria for evaluating phylogenetic relationships is particularly critical in herpetology, since in this field traditional morphometrics have often proved inadequate for the solution of many taxonomic problems.

Many techniques for the collection of serological and chromosomal material from reptiles have been employed, but most require extensive mutilation of the specimen, limiting its use in subsequent morphological analysis. Voucher specimens so damaged often are not deposited in museum collections, with the result that their identity may become debatable in future taxonomic studies.

The basal mitotic index in most reptilian tissues is low, and in order to obtain sufficient mitotic figures, previous workers have collected cells from a variety of tissues, e.g., spleen, intestine, gonad, lung, kidney and bone marrow (Bezy, 1972; Singh, 1972; King and Rofe, 1976; Paull, et al., 1976). Others (Cole and Leavens, 1971) have attempted to stress the organism, using a variety of agents, e.g., intraperitoneal injections of active yeast cultures, in order to induce increased mitotic figures in the bone marrow. However, this technique may produce erratic results (Bezy, et al., 1977; and personal experience) in addition to increased mortality.

A more satisfactory approach has been to induce peripheral leucocyte division following mitogenic stimulation. This need not involve costly 'in vitro' culturing of blood, and Baker et al. (1971, 1972) have successfully induced peripheral leucocyte division in vivo following intraperitoneal injections of phytohemagglutinin (PHA). The technique described here derives from that employed by Baker et al. (1971) with a number of modifications, most notably the handling of much smaller quantities of material.

PROCEDURE

1) Restrain the specimen and inject i.p. with a solution of phytohemagglutinin-P (Difco Ltd.) at a dosage of 26.4 µg per g bodyweight.

2) 24 hours later, repeat Step 1.

3) 72 hours after the first injection, the specimen is injected i.p. with either colchicine (0.05° solution, 0.01 ml per g. bodyweight) or Velban (0.025° solution, 0.005 ml per g. bodyweight).

4) Sacrifice specimen using diethyl ether or Halothane.

5) The heart is exposed by a small longitudinal ventral incision, the dorsal aorta cut, and blood collected by capillary action into heparinised micro-hematocrit tubes (1 mm diameter).

6) One end of the hematocrit tube is sealed with plastacine and the tube spun for 2 minutes in an MSE Micro-hematocrit centrifuge.

7) During centrifugation, the denser red blood cells sediment faster than the larger leucocytes, which form a 'buffy coat' at the interface of the red blood cells and the plasma. The tubes are cut with a diamond-tipped pen just below the interface of the red blood cells and the 'buffy coat'.

8a) The white cells are dispersed in 1-2 ml. of hypotonic 0.95° sodium citrate for 15 minutes.

b) The plasma is transfered to small tubes and stored frozen at -20°C for future serological analysis.

c) The packed red blood cells are dispersed in phosphate-buffered saline and washed three times.

9a) The swollen leucocytes are gently pelleted at 500 g and fixed by slowly layering 1 ml of fresh Carnoy's fixative (3 parts methanol and 1 part acetic acid) on the cells.

b) The pellet of washed red blood cells is resuspended in a small volume of electrophoresis buffer to which Sapponin (1 mg/ml) has been added in order to lyse the cells.

10a) The fixed leucocytes are gently pelleted at 500 g, resuspended in a small quantity of fixative and either flame-dried or air-dried (if required for banding or scanning electron microscope analysis) onto clean microscope slides soaked in ice-cold 70° ethanol.

b) After centrifugation at 500 g for 10 minutes, the hemoglobin solution is decanted from the pellet of cellular debris and made up to 0.003 M dithiothreitol (DDT, Sigma Chemical Co. London) to inhibit possible polymerization of the hemoglobins. Some hemolysates may be converted to cyanomethemoglobin by adding 0.02 ml each of 0.1 M $K_3Fe(CN)_6$ and 0.1 M of KCN to 2 ml of hemoglobin solution.

Most biochemical techniques currently employed, e.g., immuno-electrophoris, require very small ation and polyacrylamide gel electrophoresis, require very small amounts of material, and using the technique outlined above, reptiles weighing under 2 g, including southern African species of Lygodactylus and Leptotyphlops, have been successfully karyotyped, and plasma and hemoglobin collected for serological analysis.

The use of complete in vivo treatment allows the procedure to be easily adapted for field studies, the main remaining difficulty being centrifugation. This is desirable as it increases the ratio of mitotic figures to contaminating red blood cells. As reptilian red blood cells are nucleated and stain with Giemsa, it is often tedious finding suitable mitotic figures in a 'sea' of red blood cells. Leucocytes sediment slower than red blood cells in unspun hematocrit tubes; however, centrifuge speeds necessary for sedimentation are relatively low and can even be achieved with small, hand-cranked, portable models.

Species differences in the optimal time of response to PHA stimulation of peripheral leucocytes may be a complicating factor. Thus, Taylor and Bolanos (1975) observed maximum mitotic figures within a day of PHA treatment in Bothrops atrox and B. nasuta, but only after 3 and 4 days respectively in the congeners B. picadoi and B. godmani. Where the optimal period of PHA treatment cannot be determined by trial due to the availability of only a single or few specimens of a rare species, then small samples of blood can be collected on consecutive days, either from the tip of a snake's tail (Dessauer, 1970), or from the orbital sinuses of lizards (MacLean, et al., 1973). This blood can then be cultured for a short period (4-6 hr) in the presence of either colchicine or Velban, without the need for aseptic conditions. In fact, rare, desirable species may be karyotyped without sacrifice, as has been done with the endangered bog turtle, Clemmys muhlenbergi (Bickham, 1975).

Two Black Rat Snakes From One Egg

On 25 June 1977, a 50 inch (1270 mm) female Black Rat Snake (Elaphe obsoleta) was caught in Cuivre River State Park, Lincoln County, Missouri. During the early morning of 28 June, she laid eight eggs, ranging in length from 48 to 56 mm, in width from 24 to 26 mm, and averaging 51 x 25 mm.

The first hatchling appeared on 19 September. On 20 September, three more eggs were slit, and from one of these eggs two snakes stuck their heads out (see Fig. 1). Later that evening, I slit the egg a little farther and two completely separate snakes emerged. These two snakes

measured 250 and 255 mm, compared to the other seven hatchlings (the last snake hatched on 23 September), which ranged in size from 290 to 340 mm, and averaged 311 mm in length.

Notes on Three Species of Micrurus (Serpentes: Elapidae) from Mexico

During an expedition to southeastern Mexico (Summer, 1976), we collected 8 specimens of coral snakes representing three species. Since little information is available on habitats, activity periods and food items, the following data are provided.

Four specimens of Micrurus diastema were collected on roads at night in southern Quintana Roo, Mexico. Two specimens (Louisiana St. Univ. Mus. Zool. LSUMZ 33359-60) were found 16.1 km W Bacalar on 28 and 30 June 1976 at 2200-2400 hrs. A third specimen (LSUMZ 33361) was found 32.2 km N Bacalar on 1 July 1976 at 2300 hrs, and a fourth specimen (LSUMZ 33362) from 24.1 km N Bacalar on 8 July 1976 at 2300 hrs. Three of the snakes were found active on the road, and one DOR. Heavy rains had occurred from 23 to 28 June and had caused local flooding, leaving standing water in the surrounding area. Habitat is a mixture of hardwood forest, scrub forest and tall grasses. One specimen (LSUMZ 33359) contained two adult Eumeces schwartzi. The state of digestion of the two lizards indicated that one had been eaten very recently while the other had probably been ingested within a couple of hours.

Two specimens (LSUMZ 33363-64) of Micrurus diastema were also collected on the road at night at 2200-2400 hrs. on 5 July 1976 in northern Quintana Roo, 3.2 km N and 19.3 km N Playa del Carmen. The surrounding area is a mixture of deciduous trees, palms and grasses. No heavy rains had occurred in this area.

A specimen of Micrurus elegans veraepacis (LSUMZ 33366) was collected 13 June 1976 at Cascadas de Mizola, 21 km S Palenque, Chiapas (ele. 250 m). This adult female was crawling among the moist leaf litter at dusk in the rain forest.

A specimen of Micrurus browni (LSUMZ 33365) was collected 16 July 1976 at 8 km N Soyalo, Chiapas (ele. 2000 m). The snake was found on the road at 1700 hrs. Surrounding area was a deforested hillside with some conifer and deciduous trees. The coral snake had eaten two Adelphicos quadrivirgatus. One of these snakes had been eaten very recently while the other snake had probably been ingested a couple of hours earlier.

Observations on an Audio-Visual "Warning" Signal in the Pigmy Rattlesnake, Sistrurus miliarius (Reptilia, Serpentes, Crotalidae)

The cottonmouth, Agkistrodon piscivorus, predominantly utilizes a visual threat display by opening its mouth and revealing a white interior that probably serves as an effective warning device at close range (Burkett, 1966). Klauber (1972) presents strong arguments supporting the theory that the rattle of a rattlesnake serves to warn away potential predators. He also mentions that other warning mechanisms are employed in conjunction with the rattle including the hiss, use of the tongue, scent glands, and body posture.

During mid-March of 1975, while on the pine flatwoods of South Carolina, a dusky pigmy rattlesnake (Sistrurus miliarius barbouri) bobbed its head vertically and rattled in response to my approach. This same phenomenon was observed in mid-March of 1976 in the same region. In both instances, movement of the head first attracted my attention before the faintly audible sound of the rattle. Observations in the laboratory were conducted during July 1977 on a female of the above species, and on a male S. m. miliarius (Carolina pigmy rattlesnake). Both snakes were housed separately. I moved in close proximity to a cage and made rapid, threatening movements towards a snake. No tactile stimuli were offered. Both snakes responded by head bobbing and rattling. Observations conducted in the same manner during March 1976 on recently captured male and female S. m. barbouri showed the same behaviors.

Head bobbing in snakes was reported relatively early in the literature (Corrington, 1929) and has since been felt to be a common behavior for the majority of male and female North American snakes (Neill, 1949) that serves as a sign of annoyance (Burkett, 1966; Munro, 1950), but is mainly concerned with reproduction (Munro, 1950; Neill, 1949). I feel that this behavior, in conjunction with rattling, greatly enhances the warning display of S. miliarius. These actions provide subtle visual and audio signals that can function to warn different predators with different propensities towards either component of the

signal. Since the signal is subtle, it can serve to warn predators at close range without attracting the attention of animals farther away.

ACKNOWLEDGMENTS

I thank Dr. Bayard Brattstrom for reviewing the manuscript and contributing important suggestions and Ernst G. Hofmann for the loan of his S. m. miliarius.

The Status of Suppressed Names and of Callopsis Gray (Reptilia: Testudines)

One of the most secure routes to nomenclatural stability is for placement of questionable names on the appropriate "Official List" by the International Commission on Zoological Nomenclature (ICZN); and conversely, it may be concluded that an equally secure route to nomenclatural elimination is for the ICZN to place questionable names on the appropriate "Official Index." Although the latter is true so far as actual use of any given name as valid is concerned, such names can serve almost any other nomenclatural roles, unless specifically excluded from them.

A case in point is the generic name of the neotropical semiterrestrial emydine turtles, in recent years commonly referred to as Rhinoclemys Gray, 1863 (McDowell, 1964), although the last review of turtles of the world (Wermuth and Mertens, 1977: 29-33) places them subgenerically as Geoemyda (Rhinoclemmys), citing Fitzinger (1835) as author. However, Smith, Smith and Sawin (1976) argued that Gray's Rhinoclemys, 1863, is an objective synonym of Rhinoclemmys Fitzinger, 1835, intended (or at least created) merely as an emendation thereof. That view is apparently fully justified, with the concurrence of Wermuth and Mertens (1977: 28) and Fretey, et al. (1977: 64).

However, the same authors (Smith et. al.) also regarded Rhinoclemmys Fitzinger as either undesirable or unavailable for the genus (as did McDowell), because, of the two species cited by Fitzinger, one (Clemmys orbignyi Dumeril) belongs to the genus known as Pseudemys Gray, 1855 (Or Chrysemys Gray, 1844, depending upon whether the latter two groups are regarded as congeneric, but in either case antedated by Rhinoclemmys Fitzinger, 1835), and the second (Clemmys dorsata, Wagler, 1830 = Testudo dorsata Schoepff, 1801, a senior synonym of Testudo punctularia Daudin), is not only a nomen oblitum (never having been used as a valid name since Fitzinger's time) but was suppressed by Opinion 660 of the ICZN. Obviously, it would not be in the interest of nomenclatural stability to replace Pseudemys (or Chrysemys) with Rhinoclemmys, and the alternative of its use for neotropical "Geoemyda," as previously envisioned, seemed precluded by the nomenclatural inadmissability of dorsata.

The problem was actually partially resolved, as later pointed out by Fretey, et al. (1977: 64) by explicit selection by Lindholm (1929: 282-283) of "Emys dorsata Schweigger, 1812" (= Testudo dorsata Schoepff, 1801), a name cited by Fitzinger, as the type of species for Rhinoclemmys, thus eliminating the hazard to Pseudemys (or Chrysemys). Lindholm's action did not alter the situation relative to the availability of Rhinoclemmys, except to leave it dependent entirely upon a name-- dorsata --presumably nonfunctional nomenclaturally (except in cases of homonymy). Thus excluded from nomenclatural use, Rhinoclemmys should be succeeded by the next earliest available name, to wit Callopsis. At least so reasoned Smith, et al. (1976) and no doubt McDowell (1964).

However, Fretey, et al. (1977), acting upon their own analysis of the situation and the counsel of their colleagues Holthuis and Dupuis (both Commissioners), declared that mere suppression or non-use, or both, of a name does not prevent its service as type of a genus, and recognized Rhinoclemmys Fitzinger as the proper name in the present case.

Actually the Code and Official Indices give no explicit statement relative to the nomenclatural role the suppressed names may properly play. Accordingly, an inquiry was directed to the Secretary, Dr. Richard V. Melville, of the ICZN, seeking clarification of the point. He confirmed the validity of the view expressed by Fretey, et al.: a suppressed name, even if also a nomen oblitum of however great an antiquity, can still serve as the type-species of a genus, so long as it is available (and therefore occupied), the ICZN has not explicitly contraindicated, and presumably, it is identifiable (therefore not a nomen dubium). That concept, if upheld, should be incorporated in the Code, and not left to judgment.

Therefore the correct name for the genus to which Testudo dorsata Schoepff (and its validated junior synonym Testudo punctularia Daudin) belong is Rhinoclemmys Fitzinger, 1835. The species and subspecies currently recognized are:

1. Rhinoclemmys annulata (Gray), 1860
2. Rhinoclemmys areolata (Dumeril, Bibron and Dumeril), 1851
3. Rhinoclemmys funerea (Cope), 1876
4. Rhinoclemmys pulcherrima (Gray), 1855
   a. Rhinoclemmys pulcherrima pulcherrima (Gray), 1855
   b. Rhinoclemmys pulcherrima incisa (Bocourt), 1868
   c. Rhinoclemmys pulcherrima manni (Dunn), 1930
5. Rhinoclemmys punctularia (Daudin), 1802
   a. Rhinoclemmys punctularia punctularia (Daudin), 1802
   b. Rhinoclemmys punctularia diademata (Mertens), 1954
   c. Rhinoclemmys punctularia melanosterna (Gray), 1861
   d. Rhinoclemmys punctularia nasuta (Boulenger), 1902
6. Rhinoclemmys rubida (Cope), 1870
   a. Rhinoclemmys rubida rubida (Cope), 1870
   b. Rhinoclemmys rubida perixantha (Mosimann and Rabb), 1953

Feral Dog Predation of the Gopher Tortoise, Gopherus polyphemus (Reptilia, Testudines, Testudinidae) in Southeast Alabama

Between March 1972 and September 1974, free-ranging dogs (Canis familiaris) were captured in several areas of southeast Alabama and fitted with radio instrumented collars. Periodic monitoring of these dogs using telemetric devices allowed us to determine that at least 94 (86%) were feral or "wild" dogs. The primary study area was on the Fort Rucker Military Reservation in Dale and Coffee counties.

While investigating the predatory activities of these feral dogs, we encountered many burrows of the gopher tortoise Gopherus polyphemus that had been excavated, both partially and completely, apparently by one or more dogs. Though not specifically searching for excavated burrows, we identified 19 that appeared completely destroyed by feral dogs between March 1972 and November 1973. Initially, we assumed that feral dogs were seeking animals other than tortoises that might have sought refuge in the burrows. It is known that a variety of animals, including skunks, opossums, foxes, snakes, and insects use gopher tortoise burrows for dens and convenient retreats (Mount, 1975). Carr (1952) mentions animals seeking shelter in gopher tortoise burrows to escape pursuing dogs.

Several den sites of feral dogs had cracked and chewed bones and shell fragments of gopher tortoises nearby. On the morning of 5 August 1973, a pack of six feral dogs was approached after it had returned from an all-night hunting foray. They were growling, barking, and snapping in a loud, raucous manner and were so preoccupied with their activity that they allowed one of us to approach very closely. These dogs had captured an adult gopher tortoise (carapace length ca. 30 cm). Repeatedly, the tortoise was vigorously tossed into the air and allowed to fall to the ground. At this time a very large (approximately 30 kg) black and tan hound seized the tortoise and fractured the plastron and bridge, producing a loud cracking sound. One of the dogs sensed the presence of the observer, gave a sharp alarm bark, and the pack retreated. Examination of the tortoise revealed that the shell was cracked in such a manner that little effort was required to completely expose the viscera.

About 3 m away was a freshly excavated tortoise burrow about 1 m deep, presumed to have been that of the captured tortoise. Presumably, dogs could dig out tortoises from the bottoms of burrows of the average depth reported by Hansen (1963) only with considerable difficulty. However, gopher tortoises in shallow burrows and those caught away from their burrows probably are susceptible to considerable feral dog predation, since 57 feral dogs were identified in the same general area where tortoise burrows had been destroyed. Based on the size of the area occupied by these dogs, we projected the total feral dog population on the 24,000-ha military reservation to be 308 animals.

The gopher tortoise is a resident of the Lower Coastal Plain of Alabama (Mount, 1975) and is fairly common on Fort Rucker Military Reservation. This species was recently listed among "threatened" plants and animals of Alabama (Mount, 1976). The southeastern section of The Wildlife Society considers the gopher tortoise a "threatened" species. Mount (1976) stated "despite the relative abundance of gophers in some parts of the range, the species is declining markedly in overall numbers."

Predation on adult gopher tortoises, other than by man, is reportedly low (Mount, 1976; Ernst and Barbour, 1972; Douglass and Winegarner, 1977); however, Auffenberg and Weaver (1969) said that coyotes seem to predatorize adult G. ber-

HIDING BOXES
ARE BACK IN STOCK!

FURMONT REPTILE EQUIPMENT

FEATURES:

- Use For Reptiles Or Amphibians
- Made of Rugged ABS Plastic
- Strong, But Light Weight
- Opaque Pebble Grained Exterior
- Easy To Clean Or Sterilize With Liquid Cleaner
- 3 Sizes To Fit 5, 10, And 15 Gallon Tanks
- Stackable For Compact Storage

PRICE:

QUANITY	SIZE 1	SIZE 2	SIZE 3
	4" x 6" x 2"	6" x 8" x 3"	8" x 10" x 4"
1 - 9	$2.25 each	$3.85 each	$5.30 each
10 - 24	$2.15 each	$3.65 each	$5.00 each
25 - UP	$2.10 each	$3.55 each	$4.90 each

Minimum postpaid order - $15.00. Orders for less than that add $2.50 for shipping and handling. Texas residents please add 5% Sales Tax. Make checks payable to Fuhrman Diversified. Open account orders are accepted from recognized institutions, etc.

Write For Our Entire Catalog Of Reptile Equipment.

landieri. Our observations suggest that predation on gopher tortoises by some feral dog packs is significant. Feral dogs would certainly seem to be prime predators of young tortoises as well as of the nests. Further investigations of the problem are warranted.

PHOTOPERIOD AND REPTILE REPRODUCTION

INTRODUCTION

As more emphasis is placed on captive reproduction of reptiles, various factors influencing reproductive potential have been considered. At first, reptiles were kept healthy and well fed in relatively constant environments. Emphasis was on quality of diet and optimum temperature. Sex determining techniques made many aware that sex ratios including members of both sexes had to be accurately determined. Spatial requirements were given consideration and larger quarters were provided for groups of smaller animals. Quality of lighting was improved using various sources of ultraviolet radiation.

All these factors have some influence on various types of animals and their reproductive cycles. There are many environmental factors of greater or lesser significance which are now being considered. "Seasonal fluctuation in length of day - an astronomical component of geographical climate - is an important factor in determining the distribution and adaptations of organisms. The timing of seasonal biological events...may depend on the length of day, instead of the more obvious seasonal change in temperature" (Bates, 1961). "The breeding season of reptiles is primarily affected by temperature conditions and photoperiod" (Porter, K. R., 1972).

Photoperiod, by definition, is the length of time each day during which an animal is exposed to light. The effects of exposure can be negligible or severe depending on wavelength (color), intensity, changes in either of these, length of exposure time, sensory apparatus of the animal, and probably several conditions as yet unknown. Studies have shown that one of these effects can be an increase in gonadal size and hormonal activity (Aronson, 1965). Therefore, photoperiod control is being considered as another factor which might increase reproductive potential in captive animals, particularly reptiles.

Not all species, not all individuals, will respond to photoperiod control in the same way. "The importance of photoperiod seemingly varies considerably from species to species even outside of the tropics" (Porter, 1972). Obviously, animals which spend daylight hours underground and only come out after dark are not going to have the same response as those which emerge with the first rays of the sun and retire at dusk. Some species are crepuscular, emerging during daylight, but only early morning and late evening. Some regulate their temperatures by alternatively hiding and emerging. Some spend much of their lives on the dark forest floor or underground. Some species are sensitive to minute changes in light level while others can hardly see at all. Some forms even have photoreceptors sensitive to wavelengths of light which we can only detect with sophisticated equipment.

Another factor which may be difficult to control is rapidity of change. Most mechanical light controls turn on or off instantaneously while natural light goes through subtle color changes correlated with temperature, wind, and barometric changes each morning and evening and also during storms and other meteorological phenomena. All the complex factors influencing reproduction will probably never be understood or controlled for every species, but systematic advances will add more species to the growing list of those being bred in captivity now.

In an effort to present a starting point for photoperiod research, the following tables have been compiled. Using the formula, it is possible to determine with reasonable accuracy the average length of day for any latitude on any given week. Using the basic solar day, an annual photoperiod cycle can be set up approximating that of the locality of origin for a given animal. It is hoped that this will lead to experiments which will refine our theories adding more knowledge which will cycle back until working systems allow us to breed new species.

FORMULA

Astronomers have been interested in day length ever since the first star gazer noticed that he could see more stars at night than during the day. Therefore, it was logical to turn to astronomy for information on photoperiod. Astronomers determine hours of daylight at any latitude on any given week by using the formula:

$$H = 2/15 \arccos(-\tan L \tan D)$$ [1]

where D is the apparent declination of the sun for a given week as presented in the solar ephemeris (U.S. Gov't, 1076) (see chart #1) and L is the latitude in positive (+) (north of the equator) or negative (-) (south of the equator) decimal degrees. H is the decimal hours of sunlight at the latitude on the given week (converted into hours and minutes in the programs and charts).

TABLE 1.

Instructions

This table is extrapolated from the ephemeris[2] which, in its originally published form, gives the declination every three days and in degrees, minutes and decimal minutes. It was felt that for our purposes, one photoperiodic change per week should be sufficient and the formula calls for the declination in decimal degrees. Anyone wishing to compute the photoperiod for a given latitude during the year will find this table necessary.

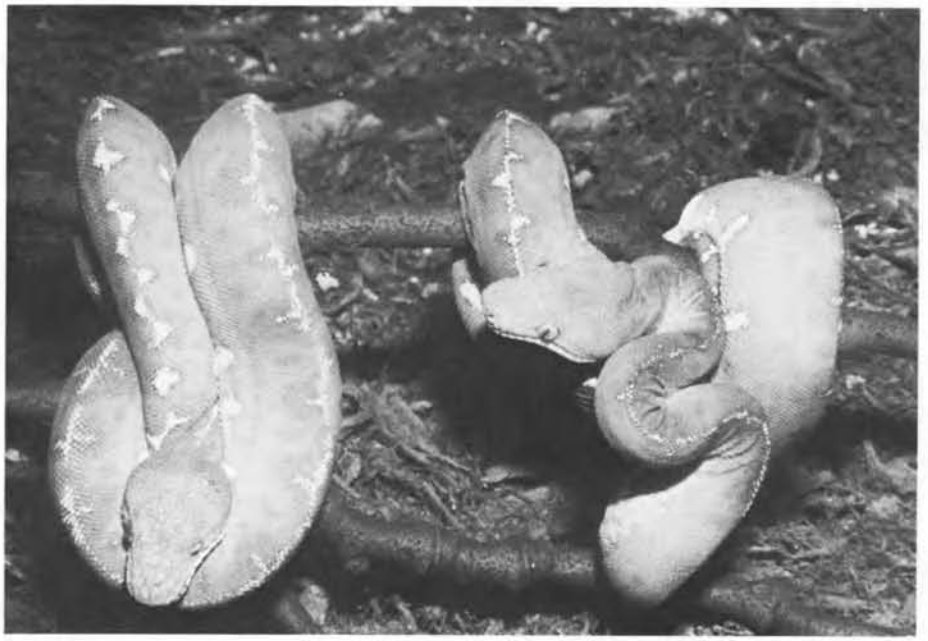
OBSERVATIONS ON THE REPRODUCTION OF THE EMERALD TREE BOA, CORALLUS CANINUS

The emerald tree boa, Corallus caninus is often exhibited in zoological collections and is indeed much sought-after for display. It is therefore surprising that the reproduction of this species is not well known. Meyer-Holzapfel (1969) reported on a captive female that produced 6 young and 3 undeveloped ova and Fitch (1970) mentioned a large female that contained 10 full termed fetuses. More recently, Murphy, et al., (In press) reported the birth of 10 young from a captive female at the Fort Worth Zoo and described these young as well as their ontogenetic color change. They also described courtship behavior in this species. Reported here are additional observations on the captive reproduction and young of this species.



The Philadelphia Zoological Garden received an adult pair of emerald tree boas in July 1973. This pair was kept in quarantine for approximately 30 days, during which time fecal samples were obtained for parasitic examination and regular feeding was established. Following this period, these snakes were moved to a large vertical fiberglass exhibit containing another female emerald tree boa and a pair of green tree pythons, Chondropython viridis, all three of which were later removed for various reasons. The enclosure, measuring 137 x 109 x 239 cm., is decorated with polyethylene vegetation and fiberglass rockwork on one wall. The rockwork forms a small "waterfall" which fills an elevated pool. A large 7.5 m dead tree with many horizontal branches has been provided and contact with this tree by the snakes is always maintained, even when they are soaking in the elevated pool. Several branches are positioned so that they overhang the elevated pool. A licorice root mulch is provided for the substrate. Moisture is added to the enclosure by misting the walls, ceiling, substrate and polyethylene vegetation twice daily (from January to March the exhibit is misted 3 or 4 times daily). These snakes are also soaked in tepid water out of the exhibit once each week to encourage defecation.

Courtship behavior was first noted between this pair in late January 1974 and continued irregularly until early March 1974. Unfortunately, all aspects of this behavior were not observed. However, on several mornings the male was coiled next to the female on one of the horizontal branches near the top of the tree. In this position he was attempting to wrap his tail around the female's tail, which was firmly coiled around the branch and protected by several coils of her body. The only observed copulation occurred on the morning of 4 February 1974, and was similar to the behavior described above (Fig. 1). This behavior differs from that reported by Murphy et al., (In press) in that no exploratory behavior of the female's body by the male's tongue or body, or the use of his spurs were observed.

Although the female fed well, she fasted from 8 May 1974 until after parturition, approximately three and one half months later, without notable weight loss. In May 1974, a slight abdominal swelling was noticed, which increased in bulk and length until 4 August 1974, when it occupied the posterior 1/3 of her body. An increase in water consumption was also noted during this period.

On 7 August 1974, between 0900 and 1030 hr., the female gave birth to 6 living young which averaged 406

mm in total length and had an average weight of 40 g. Four undeveloped ova were also produced. A relatively long umbilical cord was surgically removed from the young shortly after birth. The natal skin was shed within 48 hours of birth.

The young were colored alike, differing considerably from the adult. The top of the head and dorsum were reddish-orange and the lower labials and venter were light yellow. A white vertebral stripe with numerous lateral extensions extended from the neck to the end of the tail. A series of ventrolateral white markings were also present (Fig. 2).

Within three months of birth, two young had died. One had an infected umbilicus and the other died from intestinal atresia. All of the young refused to eat on their own and had to be assisted by gently opening their mouths and placing dead furred mice therein. Several months later, all but one (the smallest) of the remaining young began feeding on their own and assisted feeding was stopped for these specimens.

By December 1974, four months after birth, three of the four remaining young started to develop the emerald green coloration of the adult. The fourth young, the smallest specimen, did not begin color transformation until March 1975. Approximately 1 1/2 to 2 months were required for the color transformation to be completed.

In March 1976, a young captive-bred male emerald tree boa from the Fort Worth Zoo was introduced with our female on exhibit. Although courtship behavior similar to that reported by Murphy et al., (In press) was noted shortly after introduction, no copulations were observed. The female was later removed from exhibit in June 1976 for medical reasons.

During August 1976, an abdominal swelling was again noted in the female, which increased in size and bulk until the end of December 1976, when it occupied the posterior 1/3 of her body. An increase in water consumption was not noted during this period, but this might be due to the fact that the holding facility did not have the observational qualities of the exhibit.

On 2 January 1977, at approximately 1400 hr. the female gave birth to 10 dead and 1 live young, as well as producing 3 undeveloped ova. None of these young were measured or weighed; however, they appeared to be similar in size and coloration to the young produced in 1974.

The single live young was immediately put in a clean, warm gallon jar with damp paper towels to provide an abundance of humidity. This snake was then transferred to a small aquarium after four days when it appeared to have gained some strength. A small horizontal branch was provided for resting purposes. Although this snake was kept in a warm room where humidity is approximately 75 to 80%, a damp paper towel was kept in the cage with the snake to provide additional humidity. The natal skin of this specimen was shed approximately 48 hr. after birth. The long umbilical cord was surgically removed during this 48 hr. period.

This specimen refused to eat on its own and was assisted by placing newborn mice in its mouth, with swallowing occurring voluntarily. This specimen died on 24 March 1977, for unknown causes.

ACKNOWLEDGMENTS

I would like to thank Kevin Bowler and Harry W. Greene for their helpful comments in preparing this manuscript. I would also like to thank James B. Murphy for sending me a copy of his manuscript on reproduction of boas, which is presently in press.

TO CATCH A CROCODILE: HUNTING IN PAPUA/NEW GUINEA. By Peter Pinney, 145 pages. Angus and Robertson, London, 1976. $4.00.

The people of Papua/New Guinea's gulf delta area and those inhabiting the borders of the massive Fly and Sepik river systems are traditional consumers of crocodiles. Prior to European contact, these special crocodile-hunting communities enjoyed an ecologically balanced relationship with their wildlife. Then, in the early 1950's, expatriate hunters discovered the enormous potential of New Guinea's crocodile resource and began to compete with the indigenous peoples for their wildlife. Introduced rifles, shotguns, electric torches, gill nets, outboard motors, and assorted hunting paraphernalia were the tools of destruction which crippled Papua/New Guinea's crocodile populations during the twenty-year period that followed.

One of those expatriates who participated in the slaughter was George Craig, a large, tough man who, by his own admission, processed some 29,000 crocodile skins in his salting shed in Daru during fifteen exploitive years. To Catch a Crocodile is the portrayal of Craig's last big hunt on the Fly. Craig embarks from his headquarters on Daru, an island off the south coast of Papua/New Guinea, in his forty-five foot vessel, the Janis B. With his Creole associate, Copian, Peter Pinney (the book's author--smuggler and self-proclaimed conservationist), and several indigent helpers, Craig skillfully navigates his craft on a 500-mile Fly River venture.

The journey leads the group in search of remnant populations of crocodiles in sheltered lagoons and tiny river systems which feed the Fly. Searching for an eterari, a twenty foot monster crocodile, Craig and company violate the traditions of the Mipan River people and enter their forbidden and enchanted Mamoosie Swamp. They pass villages where hollow remnants of humanity have lost their traditions and livelihood in the course of interacting with white crocodile hunters, missionaries, and assorted exploiters. Money is doled out to natives who clamber onto the deck of the Janis B with crocodile hides, to be exchanged later for trinkets from the ship's store.

This, the last hunt, had to be a big one. The crocodile resource was evaporating in the Fly system, and Craig decides to culminate the adventure by leading an expedition to a previously unexploited swamp across the Irian Jaya (Indonesian New Guinea) border. Abandoning common sense and the mother ship, the group sets forth in tiny skiffs on an incredibly arduous westward journey. True to Craig's predictions, they found crocodiles in abundance. Suddenly, before the savage harvest could begin, the alien visitors are discovered. Facing poaching charges at the very least, the group wildly retreats back toward the Fly, followed by a wind-driven inferno set by their pursuers. The author, a talented composer of descriptive passages, summarizes the view behind them, "It was as if the womb of the mighty Fly, the swamps which nourished her, lay bleeding and prostrate from some frightening abortion."

Indeed, To Catch a Crocodile is an authentic and masterfully written book, which provides its readers with insight into the integration of the lives of crocodiles, expatriates, and the exploited indigents of Papua/New Guinea. Unfortunately, the book's hero is typical of the human parasites who ravaged the country's resources and the minds of its inhabitants. It seems enigmatic that the author should attempt to convince his readers that Craig is a sensitive conservationist concerned about the future of Papua/New Guinea's wildlife.

JOHN BEHLER, Curator of Herpetology, New York Zoological Society, Bronx, New York 10460. ●

AMPHIBIANS & REPTILES IN ALASKA, THE YUKON & NORTHWEST TERRITORIES. By Robert Parker Hodge. 1976. Alaska Northwest Publishing Co., Anchorage, Alaska. x + 89 pp., illus. $3.95.

Robert Parker Hodge has produced an appealing regional handbook of herpetofauna. His paper-covered, pocket-sized book is colorful, well-illustrated with both black-and-white and color photographs, line maps and drawings. It is especially aimed at the non-specialist, but I found its text informative and well-written for specialists as well. As more people are visiting and living in the northern part of the continent, it is time for a general, regional handbook of herpetofauna.

Having so few species in the local fauna was an advantage to Hodge, for it allowed him to consider other than the usual subjects included in most treatments of regional faunas. Major subjects are: basic information about amphibians and reptiles, geographical distribution and origin, northern adaptations, mythology, physiography, climate, habitat types, check lists and species accounts, and suggestions for study. Species found in Alaska are treated separately from those found in Yukon and the Northwest Territories. Only one species, the wood frog, is known to occur in both Alaska and also in northern Canada.

Six species of amphibians and one reptile are known to occur in Alaska. Only one species, the wood frog, is widespread, and only three species occur north of the Panhandle. Three species of frogs, two toads, and one snake are known to occur in the poorly-explored Northwest Territories and Yukon. Certainly the list of Tongass Museum specimens is an indiction of how little is known about the distribution of these species. Virtually nothing is known about other aspects of their biology in the North.

An important section of the book explains how these species may have gotten where they are. Hodge's general explanation of continental drift and past climatic changes is clear, and his presentation of the problems of adaptation of ectothermic vertebrates to northern climates is fine. The list of unsolved problems concerning these adaptations is a challenge to students for further research.

I like the section on "Mythology, Religion, and Superstititon." But I wished for more of the centuries-old legends of the Alaskans concerning the role of Frog and Salamander in their totemic religions. The reader is teased by the interesting photographs and references to many legends. It is not clear why warnings concerning problems encountered during collecting and ill-used tact-

ics of politicians should be included in this section.

I found only two typographical errors in the book (Plethodon becomes Phethodon on p. 78 and Brina Kessel becomes Brian on p. 86). Two illustrations lack captions (p. 17, 18). I would have liked references at the ends of appropriate sections, preferably with citations in the text. It is not clear whether the "Reading List" includes all sources for information in the text. There is no taxonomic key for identification; however the fine illustrations and the distinctness of the species makes identification easy from the photographs alone.

Hodge, a six-year resident of Alaska, stresses the need for information about the biology of northern populations. His book should stimulate further sutdy of these special peripheral populations. The call to amateurs to contribute to the scarce information about amphibians and reptiles in the Far North is an important statement. Especially pertinent is the warning that these animals keep poorly in captivity. Except for possibly brief observations on captive animals, amateurs are discouraged from keeping amphibians and reptiles in captivity.

Hodge has produced an attractive, informative, and stimulating book which is an important contribution to the scarce natural history literature about Alaska. Even if the reader never goes to the Far North, he will have gained much by spending an hour or two with "Amphibians & Reptiles in Alaska, the Yukon & Northwest Territories." And the price is right!

MARGARET M. STEWART, Department of Biological Sciences, State University of New York at Albany, Albany, New York 12222. ●

Legislative Alert

LEGISLATIVE NEWS:

Since the last issue, the following rulemaking actions have taken place --

Proposed regulations:

1) The U.S. Fish and Wildlife Service proposed to determine the Key mud turtle (Kinosternon bauri bauri) and the Plymouth red-bellied turtle (Chrysemys rubriventris bangsi) to be Endangered species and to identify Critical Habitat for these species (F.R., Vol. 43, No. 98, 19 May 78). Public comment period closed 18 July 78.

2) The U.S. Fish and Wildlife Service proposed Critical Habitat for the hawksbill sea turtle (Eretmochelys imbricata) in the Commonwealth of Puerto Rico (F.R., Vol. 43, No. 101, 24 May 78). Public comment period closed 23 July 78.

3) The U.S. Fish and Wildlife Service proposed Critical Habitat for the Santa Cruz long-toed salamander (Ambystoma macrodactylum croceum) in California (F.R., Vol. 43, No. 121, 22 June 78). Public comment closed 22 July 78.

Final regulations:

The National Marine Fisheries Service (NMFS) and U.S. Fish and Wildlife Service have determined the loggerhead sea turtle (Caretta caretta) to be a Threatened species. In addition, the green sea turtle (Chelonia mydas including subspecies C. m. agassizii and C. m. carrinegra) and the (olive) Pacific ridley sea turtle (Lepidochelys olivacea) are determined to be Threatened species, except for Florida and Mexican Pacific coast breeding populations of C. mydas and Mexican Pacific coast breeding populations of L. olivacea, which are Endangered species (F.R., Vol. 43, No. 146, 28 July 78). This ruling becomes effective 30 days after publication of the "availability of EPA's impact statement."

NOTICE:

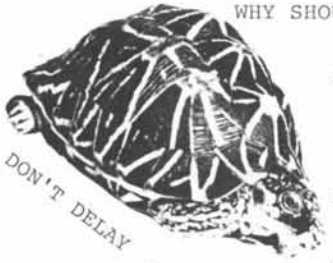
In order to combat complaints by some of our colleagues that they are not receiving adequate notice of U.S. Federal and state legislative actions involving amphibians and reptiles, the SSAR has established the Legislative Alert Committee. Its objective is to rapidly circulate such legislation among U.S. herpetologists, who can then prepare adequate responses to the rulemaking within the required public comment period. The following is a brief description of how this needed information flow should operate--

Federal legislation: contacts in Federal agencies supply the Legislative Alert Committee Chairperson with a copy of the proposed legislation or rulemaking (NOTE: all wildlife legislative actions are published in the Federal Register which is available in any law school library). The chairperson then calls the regional committee representatives (see below for names and addresses) to inform them of the legislation. Each regional rep in turn should contact SSAR state representatives and/or regional societies within his/her region, and each state/regional society representative will then inform the herpetologists in their state/society. As soon as they are available, copies of the legislation are disseminated to herpetologists following the lines described above.

State legislation: state SSAR representatives and/or regional society members are encouraged to inform the committee chairperson of any "herp" legislation or rulemaking within their states. The chairperson then calls the committee's regional reps, who in turn will call the state/regional society representatives (other than the one reporting the legislation originally) who call the herpetologists in the state and/or regional societies. Copies of the state rulemaking are circulated to herpetologists as it becomes available along the lines described for Federal legislation. Herpetologists outside those states proposing legislation need to be informed, as many have knowledge of a species involved.

The SSAR Legislative Alert Committee is composed of the persons listed below; these individuals are responsible for keeping herpetologists informed of legislative actions in those states following their names.

Hugh Quinn, Chairman Curator of Herpetology Houston Zoological Garden P. O. Box 1562 Houston, Texas 77001	TX AR LA
Malvin L. Skaroff 1025 Lakeside Avenue Philadelphia, PA 19126	CT DE ME MA MD NJ NY PA RI VA WV DC VT NH
Norman Scott Department of Biology University of New Mexico Albuquerque, N. M. 87106	AK ID HI OR WA CA NV CO MT WY UT AZ NM
Tom Berger Museum of Natural History University of Kansas Lawrence, Kansas 66045	IA KS MO NB ND SD IL IN MI MN OH WI KY
Howard (Duke) Campbell Gainesville Field Station USDI, F. & W. S. 2820 E. University Avenue Gainesville, FL 32601	AL FL MS GA PR NC SC TN



Copies of all letters sent in response to legislative actions should be forwarded to Hugh Quinn.

In order to document the committee's effectiveness over the next year, please let Hugh know if you are not receiving notice of legislative actions prior to seeing it in this column.

THOMAS J. BERGER, Museum of Natural History, University of Kansas, Lawrence, Kansas 66045. ●

SSAR Directory of Regional Herpetological Societies

The SSAR, through the efforts of its Committee on Regional Herpetological Societies, is attempting to establish a much closer relationship with those societies. In order to accomplish that end, questionnaires were sent to all of the societies for the purpose of compiling a current list and to gain some input as to how SSAR might be of greater assistance to regional societies.

The Committee chairperson, Tom R. Johnson, prepared questionnaires which covered the following topics: status of the society, hierarchy of the organization, membership, publications, frequency of meetings, and other pertinent information. The response reflects the amount of information that was returned. The status of many societies could not be determined so any corrections or additions would be welcome. Please send all information to:

Geographic Distribution

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same. The standard format for a geographic distribution record is:

Scientific name (common name) as it appears in Standard Common and Current Scientific Names for North American Amphibians and Reptiles (Collins, Huheey, Knight and Smith, 1978). Locality (use metric for distances). Date and collector(s). Identified or verified by. Place of deposition and catalogue number. Comments. Citation. Submitted by (give name and address).

Please submit new geographic distribution records in the standard format only to Joseph C. Mitchell, Department of Biology, Virginia Commonwealth University, Richmond, Virginia 23284. Short manuscripts are only acceptable when data cannot be adequately presented in the standard format.

Recommended citation for new geographic distribution records appearing in Herpetological Review is: Jones, J. 1977. Geographic distribution: Rana pipiens. SSAR Herp. Review 8(1): 1.

CAUDATA

DESMOGNATHUS AURICULATUS (Southern Dusky Salamander). USA. TEXAS: Dallas Co: 3.2 km W Carrollton. Spring 1954. L. S. Roberts. Identified by W. Seifert. Dallas Mus. Nat. Hist. DMNH 2928-2931. Extends range 160.9 km W of previous western-most range (Dial, 1965. Southwest. Nat. 10(2): 143-144. The meristic data conforms to data given by Cook & Brown (1974. J. Herp. 8(1): 93-105) for Desmognathus auriculatus; however, these specimens were recently catalogued from the Southern Methodist University collections and their body pattern has faded out.

Submitted by WAYNE SEIFERT and DOUG WUERCH, Dallas Museum of Natural History, P. O. Box 26193, Dallas, Texas 75226.

DESMOGNATHUS OCHROPHAEUS (Mountain Dusky Salamander). USA. TENNESSEE: Campbell Co: 26.7 km S Jellico (Pine Mountain area). 16 March 1976. M. A. Morris, L. M. Page, B. M. Burr. Verified by P. W. Smith and M. A. Morris. Illinois Nat. Hist. Survey. INHS 10254. Extends range south from Kentucky into western

part of Tennessee Appalachians (Tilley, 1973, Desmognathus ochrophaeus, Cat. Amer. Amphib. Rept.: 129). Also observed at Hillton, McCreary County, Kentucky on same date, but specimens escaped.

Submitted by MICHAEL A. MORRIS, Illinois Natural History Survey, Urbana, Illinois 61801. ●

PSEUDOTRITON RUBER (Red Salamander). USA. FLORIDA: Hamilton Co: Suwannee River Floodplain along Rt. 135, 2 km E White Springs. 17 June 1976. W. Auffenberg. Florida State Museum, UF 39310. Extends range for this species into northern peninsular Florida. Nearest records to the west are from the Ochlockonee River drainage in the vicinity of Quincy, Gasden Co., Florida, a distance of 179 km (Carr, 1940, A Contribution to the Herpetology of Florida, Univ. Florida Press, Gainesville). Nearest records to the north are along the Altamaha River, 8.8 km N Jesup, Wayne Co., Georgia, a distance of 167 km (Martof. 1975. SSAR Cat. Amer. Amph.Rept., 167.1).

Submitted by PETER MEYLAN, Florida State Museum, Gainesville, Florida 32611. ●

ANURA

BUFO ALVARIUS (Colorado River Toad). USA. NEW MEXICO: Hidalgo Co: 23.2 km S Animas. 21 July 1977. E. L. Peters and Paul S. Freed. Verified by C. J. McCoy. Carnegie Mus. Nat. Hist., CM 66199. Extends range eastward from 1.8 km W and 1.4 km N Rodeo, Hidalgo County (Cole, 1962, Herpetologica 18(3): 172-175). First record from Animas Valley.

Submitted by ERIC L. PETERS and C. J. MCCOY, Carnegie Museum of Natural History, Pittsburgh, Pennsylvania 15213.

BUFO VARIEGATUS (No common name). CHILE. Ofqui Isthmus of the Taitao Peninsula, (46° 42' S, 74° 5' W): 174 km SW Puerto Aysen, 4m - 100m elevation, 1 February 1976, G. Mann. Universidad Austral de Chile, IZUA N° 1661 - A. Previously known only from zones 400 m above sea level and from two areas in Chile; between 38° and 41° S and between 49° and 52° S. The specimens reported here fill the hiatus between these areas and amplify the elevational range of this species.

Submitted by GUILLERMO MANN, Wildlife Ecologist, Director of the Departmento de Conservacion del Medio Ambiente, CONAF, Ministerio de Agricultura de Chile, AV. Bulnes 285, Santiago, Chile. ●

TESTUDINES

EMYDOIDEA BLANDINGI (Blanding's Turtle). USA. NEW YORK: Jefferson Co: French Creek Marsh, 6 km SW Clayton. 7 August 1976. P. J. Petokas and M. Wasielewski. NEW YORK: Jefferson Co: N shore of Wellesey Island, Township of Orleans, St. Lawrence River. 22 August 1976. H. Miller. Roosevelt Wildlife Collection, SUNY College of Environ. Sci. and Forestry, 5512-5513 respectively. NEW YORK: Jefferson Co: Kring Point road N of Route 12, Township of Alexandria. 23 June 1977 and 27 June 1977. P. J. Petokas. Collection of P. J. Petokas, EB/6 and EB/8 respectively. Verified by M. M. Alexander. NEW YORK: Jefferson Co: Marshes of Goose Bay, Township of Alexandria, St. Lawrence River. 24 May 1977 to 9 August 1977. P. J. Petokas. 14 individuals collected, marked, and released. This report provides more precise locality information than is presently available for eastern known limits of range (McCoy, 1973, Cat. Am. Amphib. Rept. 136: 1-4). Known range should include the St. Lawrence River marshes of northern New York within the townships of Clayton, Orleans, and Alexandria, Jefferson County. Unverified observations and field data suggest that range extends inland to innermost extensions of St. Lawrence River tributaries and their associated marshes lying within the above townships along the river. Observation of a road-killed female bearing shelled, oviducal eggs on Interstate 81 South (mile 162, marker 1323), 27 km inland from the St. Lawrence River on 20 June 1977 suggests that range extends much farther inland than is presently known.

Submitted by PETER J. PETOKAS and MAURICE M. ALEXANDER, Department of Environmental and Forestry Biology, SUNY College of Environmental Science and Forestry, Syracuse, New York 13210. ●

MALACLEMYS TERRAPIN TERRAPIN (Northern Diamondback Terrapin). USA. NEW YORK: Westchester Co: Hudson River mile 43 at Indian Point 2 specimens: 8 August 1977, 12 October 1977. R. Kakerbeck. Verified by J. L. Platt. Museum of the Hudson Highlands, uncatalogued to date. This locality is 18 river miles N of the only other recent record of this species in the Hudson River (Boyle, R. H., 1969. The Hudson River-A Natural and Unnatural History. W. W. Norton and Company, New York. 304 pp.).

Submitted by JERRY L. PLATT, Curator, Museum of the Hudson Highlands, Cornwall-on-Hudson, New York 12520. ●

MALAYEMYS SUBTRIJUGA. USA. NEW MEXICO: Sierra Co: Elephant Butte Dam, 11.66 km NE Truth or Consequences. May 5, 1968. W. W. French. Verified by C. J. McCoy. New Mexico St. Univ. 4241. This species is native to southeast Asia (Schmidt and Inger. 1957. Living Reptiles of the World, Doubleday and Co., Inc., Garden City, New York) and this specimen obviously represents a release, as the species gets into the pet trade with fair frequency (C. J. McCoy, pers. comm.).

Submitted by ANDREW H. PRICE and DANE G. JOHNSON, Department of Biology, New Mexico State University, Las Cruces, New Mexico 88003. ●

SAURIA

HEMIDACTYLUS GARNOTI (Indo-Pacific Gecko). USA. FLORIDA: Martin Co: Hobe Sound. 19 October, 13 November 1977. S. Myers and W. Hutchinson. FSM/UF 41500-1503. Verified by W. Auffenberg. This locality lies ca. 139 km N of Miami record (King and Krakauer, 1966, Quart. J. Fla. Acad. Sci. 29(2): 144-154). UF 41503 was gravid, 85 mm TL, and laid 2 eggs, 25 November 1977. Geckos collected on a building next to landscaping outlet. Undoubtedly pop. started by individuals brought in on exotic plants. Indian River Co: Wabasso Beach, Barefoot Lane. 26 July 1976. M. McGranahan. FSM/UF 39065. Locality lies 231.6 km N of Miami record (King and Krakauer, 1966, Quart. J. Fla. Acad. Sci. 29(2): 144-154). Specimen appears to be newborn hatchling. Gravid female may have been inadvertently introduced by South Floridans.

Submitted by STEVEN MYERS, Indian River Community College, Mueller Center, Vero Beach, Florida 32960. ●

HEMIDACTYLUS TURCICUS (Mediterranian Gecko). USA. FLORIDA: Indian River Co: Winter Beach, 7.6 km N Vero Beach. 26 October 1977. S. Myers. FSM/UF 41415-41499. Verified by W. Auffenberg. Sebastian, S. Myers and W. Hutchinson, observed only. Winter Beach population lies 336.7 km south of Jacksonville record (Meylan, P. 1977. SSAR Herp. Review 8(2): 39) and 223.1 km north of the Miami record (Barbour, 1936, Copeia, 2: 113.). Geckos were found on a building which was formerly a landscaping outlet. Probably brought in on exotic plants.

Submitted by STEVEN MYERS, Indian River Community College, Mueller Center, Vero Beach, Florida 32960. ●

ANOLIS SAGREI (Brown Anole). USA. FLORIDA: St. Lucie Co: Ft. Pierce, S. Phillips, observed only. Indian River Co: Vero Beach, Leon Ave. 29 November, 15 December 1977. S. Myers. FSM/UF 41504-51505. Verified by W. Auffenberg. Found on Sabal palmetto. Locality lies 281.5 km south of St. Augustine record (Meylan, P. 1977. SSAR. Herp. Review

9(2): 39), and 117.4 km north of Riviera Beach pop. (King, 1960, Quart. J. Fla. Acad. Sci. 23(1): 71-73.

Submitted by STEVEN MYERS, Indian River Community College, Mueller Center, Vero Beach, Florida 32960. ●

CNEMIDOPHORUS SCALARIS SEPTEMVITTATUS (Plateau Spotted Whiptail). USA. TEXAS: Terrell Co: 33 km N Sanderson. 18 Aug. 1953. J. M. Selander and R. B. Selander. Verified by M. A. Morris. Illinois Nat. Hist. Survey, INHS 7302-7304. County record, extends range ca. 130 km NE nearest locality (Raun and Gelbach, 1972, Amphibians and reptiles in Texas, Bull. #2, Dallas Mus. Nat. Hist.).

Submitted by MICHAEL A. MORRIS, Illinois Natural History Survey, Urbana, Illinois 61801. ●

SERPENTES

MASTICOPHIS FLAGELLUM (Shaw) (Coachwhip). MEXICO: BAJA CALIFORNIA SUR: Isla Danzante: 25° 47' N, 111° 15' W. 10 July 1976. M. J. Wong. Verified by R. L. Goodrich and R. W. Murphy. California Acad. Sci. The specimen is a complete skin. Isla San Marcos: 27° 13' N, 112° 06' W. 28 and 30 May 1976. J. Myhan and R.L. Goodrich. Verified by R.W. Murphy. California Acad. Sci., CAS 141791 and CAS 143407 respectively. Scale counts and color pattern are within the variability described by Wilson (1970, Tulane Stud. Zool. Bot. 16(2): 31-99). The San Marcos specimens are characteristic of M. f. fulginosus (Cope).

Submitted by ROBERT L. GOODRICH, ROBERT W. MURPHY, JIM NYHAN and MICHAEL J. WONG. RLG, RWM, and MJW: Biology Department, University of California, Los Angeles, 405 Hilgard Avenue, Los Angeles, CA 90024. JN: 353 2nd Avenue, Colma, CA 94014. ●

LAMPROPELTIS PYROMELANA PYROMELANA (Arizona Mountain Kingsnake). USA: NEW MEXICO: Sierra Co: 2.66 km W Chloride. July 5, 1975. A. D. Thomas, Jr. Verified by A. H. Price. Alive in the collection of the latter. Extends range of the subspecies from the Arizona border 126 km eastward to the eastern edge of the Gila National Forest and the Black Range (Stebbins. 1966. A Field Guide to Western Reptiles and Amphibians, Houghton-Mifflin Company, Boston).

Submitted by ANDREW H. PRICE and DANE G. JOHNSON, Department of Biology, New Mexico State University, Las Cruces, New Mexico 88003. ●

LAMPROPELTIS TRIANGULUM CELAENOPS (New Mexico Milk Snake). USA: NEW MEXICO: Lincoln Co: Roadrunner Ranch, 53.3 km E Corona. July, 1976. W. Brett Whitford. Verified by A. H. Price. Carnegie Museum, CM 65970. First record for county, extends range of the subspecies 57 km SE of previously recorded locality (Williamson, 1972. Geographic Distribution: Lampropeltis triangulum celaenops. SSAR Herp. Review 4(5): 171).

Submitted by ANDREW H. PRICE and DANE G. JOHNSON, Department of Biology, New Mexico State University, Las Cruces, New Mexico 88003. ●

BOTHROPS YUCATANICUS (Yucatan Hognose Viper). BELIZE: CAYO DISTRICT: Benque Viejo. A. Versanel. U.S. National Museum, USNM 61781. Previously identified as Trimeresurus (=Bothrops) yucatanicus (Schmidt, 1941, Zool. Ser. Field Mus. Nat. Hist., 22(8): 475-510). Neill (1965, Bull. Florida St. Mus. Biol. Ser., 9(3): 77-130) summarized that Schmidt's specimen was B. nasutus and was followed by Henderson and Hoevers (1975, Milwaukee Publ. Mus., Contrib. Biol. Geol. 5: 1-63). Re-examination of the specimen confirms its identity as B. yucatanicus and establishes the presence of the species in Belize. Benque Viejo is some 300 km southward from the Tepich-Dziuche area of Quintana Roo, Mexico, which was previously the southernmost known locality (two specimens in the Museum of Natural History, University of Kansas, KU 157667-68).

Submitted by JAMES R. MCCRANIE, 10770 S.W. 164th Street, Miami, Florida 33157 and LOUIS PORRAS, 12120 S.W. 180th Street, Miami, Florida 33177. ●

CROTALUS RUBER LUCASENSIS Van Denburgh (San Lucan Diamond Rattlesnake). MEXICO: BAJA CALIFORNIA SUR: Isla Danzante: 25° 47' N, 111° 15' W. 10 July 1976. R. L. Goodrich. Verified by R. W. Murphy. California Acad. Sci. 143480. (Two previously collected specimens, unreported in the literature, are deposited at the California Acad. Sci., CAS 140096 and CAS 140366.) All meristic counts agree with description of the subspecies (Klauber, 1972, The Rattlesnakes, vol. 1, Univ. Calif. Press, Berkeley).

Submitted by ROBERT L. GOODRICH, ROBERT W. MURPHY, JIM NYHAN and MICHAEL J. WONG. RLG, RWM, and MJW: Biology Department, University of California, Los Angeles, 405 Hilgard Avenue, Los Angeles, CA 90024. JN: 353 2nd Avenue, Colma, CA 94014. ●

CROTALUS VIRIDIS ssp. (Western Rattlesnake). USA: COLORADO: Rio Blanco Co: Piceance Basin, Barcus Creek, Sec. 27, T2N, R98W. 6 July 1976. D. J. Freddy and J. L. Kogutt. Verified by H. M. Smith. Univ. Colorado Mus. UCM 51485. Eight rattlesnakes were observed in the Piceance Basin June through August, 1976. To our knowledge these are the first rattlesnakes observed in this Basin. Seven snakes were observed along Piceance Creek and one snake was collected (6 July) in Barcus Creek. Taxonomic characteristics of the specimen collected are intermediate between C. v. concolor and C. v. viridis (H. M. Smith, pers. comm.). Taxonomic status of rattlesnakes in northwestern Colorado is confusing. Klauber (1972, Rattlesnakes, their habits, life histories, and influence on mankind. Vol. I: 50, 51, 61) indicates C. v. concolor resides near the Basin and C. v. viridis exists disjunctly to the north. Smith, et al. (1965, Univ. Colo. Ser. Biol. 15: 22) and Stebbins (1966, A field guide to western reptiles and amphibians. p. 262) recognize only C. v. concolor in northwestern Colorado. This note is a contribution from Federal Aid in Wildlife Restoration, P-R Project W-38-R Colorado.

Submitted by DAVID J. FREDDY and JEFFREY L. KOGUTT, Colorado Division of Wildlife, Kremmling, Colorado 80459. ●

A Second Mexican Specimen of Crotalus willardi obscurus From the Sierra San Luis, Chihuahua, with Comments on other Members of the Herpetofauna

On 18 July 1977, we collected a specimen of Crotalus willardi obscurus Harris, 1974 at 1980 m in a small canyon extending north from the Canon del Oso, 11.6 km NW Rancho San Francisco on the eastern side of the Sierra San Luis, Chihuahua, Mexico. This specimen represents the second record for this subspecies from Mexico. It was found coiled on a rock in the bottom of the canyon in an area covered by oaks and carpeted with oak leaves.

The specimen, in the collection of the senior author, is a juvenile female 280 mm in total length and exhibits the following characteristics: ventrals, 152; subcaudals, 24; scale rows 27-25-19; dorsal ground color pale brown anteriorly grading to brownish-gray posteriorly; body blotches, 26, more prominent posteriorly; interspaces pale pink; some scattered black spots the entire length of body; head pale brown with a few scattered black spots on the dorsum; last four supralabials pale pink (remnant of the lower facial stripe); one tail blotch evident; remainder of tail black, horizontal tail stripes barely evident.

Harris and Simmons (1976) reported the first Mexican specimen of

C. w. obscurus from the western slope of the Sierra San Luis. Our specimen from the eastern slope suggests that the snake may be widespread in the wooded canyons of the range.

Bogert and Degenhardt (1961) mentioned that, in the Animas Mountains of New Mexico, "it is improbable...that C. rotalus lepidus klauberi, primarily an inhabitant of rocky aras, occurs in the wooded habitat occupied by C. w. silus" (= C. w. obscurus). We collected, however, two specimens of C. l. klauberi at elevations of 1960 and 2010 m, both coiled among oak leaves in the bottom of canyons in the same habitat in which the C. w. obscurus was found. However, the slopes above the canyon were rocky and C. lepidus probably occurs there, but our specimens may have retreated to the cooler canyon bottoms to escape the hot, dry conditions existing at the time of our visit.

Other reptiles and amphibians found in the general area of the Canon del Oso are as follows: Hyla arenicolor (tadpoles); Cnemidophorus exsanguis; Sceloporus jarrovi; S. virgatus; Urosaurus ornatus; masticophis bilineatus (seen); Crotalus molossus (photographed and released).

All material is to be deposited in the Museum of Zoology at Louisiana State University.

STERNOTHERUS MINOR (REPTILIA, KINOSTERNIDAE) IN THE PASCAGOULA RIVER SYSTEM, MISSISSIPPI

Apparent absence of the loggerhead musk turtle, Sternotherus minor, in the Pascagoula River System of eastern Mississippi has been a zoogeographic enigma. Tinkle and Webb (1955, Tulane Stud. Zool. 3(3): 53-67), Tinkle (1958, Ibid. 6(1): 1-56), and Iverson (1977, Copeia (3): 502-517) all concluded the species is absent from the Pascagoula. During the period 4-9 July 1977, we collected both Sternotherus minor peltifer (CM 65562-65566) and S. carinatus (CM 65545-65561) from the Chickasawhay River (main eastern branch of the Pascagoula), 4.8 km W Waynesboro, Wayne, Co., MS.

Discovery of S. minor in the Pascagoula drainage has both systematic and zoogeographic significance. Tinkle and Webb (op. cit.) separated S. carinatus and S. minor, and suggested that they may be sympatric. Although most authors have accepted this scheme, the microsympatric Waynesboro occurrence provides the ultimate corroboration. Iverson (op. cit.) hypothesized an upland route, involving capture of western tributaries of the Tombigbee River, to explain the presence of minor in the Pearl River west of the Pascagoula. This collection suggests direct dispersal through the Pascagoula headwaters as a more likely route. Finally, this collection confirms the conclusion of Tinkle and Webb (op. cit.) that the type-locality of minor lies in the Pascagoula drainage.

ACKNOWLEDGMENTS

Field work supported by the Netting Fund, Carnegie Museum of Natural History (CM). Marsha K. Christianson assisted in the field; John B. Iverson commented on the manuscript.

News Notes

GROUND BROKEN FOR REPTILE HOUSE

On 10 April 1978, after three years of design and planning, the Roeding Park Zoo, Fresno, California has broken ground on its first major herpetology facility.

The attractive 5,800 square foot adobe building contains 31 specially designed electronically controlled environmental chambers. These totally portable units can be individually programmed to control temperature, humidity and light cycle for any reptile or amphibian's needs. Each unit contains its own compressor, thermal alarms, programmable timer, and separate humidity source and controls. Special, full-spectrum flourescent lights are rheostatically controlled to duplicate the rising and setting of the sun. Complete flexibility of daylight cycle is achieved.

Additional features include separate spare amphibian and reptile rooms, each with their own temperature control; a quarantine room; moveable wall panels to allow total flexibility in display presentation; and a remote rear-projected audio-visual presentation, which is narrated, concerning behavioral or physiological information about herptiles.

The grounds around the facility are profusely planted with over 300 trees and shrubs set among large boulders and logs. A naturalistic turtle pond will be presented, complete with its own biological filter built into the pond bottom.

Completion date is set for 26 October 1978, and public viewing is planned for 1 January 1979.

INFORMATION ON HERPS OF EL SALVADOR NEEDED

Sr. Hugo Hidalgo (Ave. San Jose No. 374, Col. El Refugio, San Salvador, El Salvador, Central America) is preparing a field guide to the herps of El Salvador. He would appreciate hearing from anyone with field data, range data, photos, etc. involving herps of this area.

THE CHAMAELEON RESEARCH CENTER

Old World chamaeleons have been imported for the pet trade for many years. Last year over 20,000 Jackson's chamaeleons were exported from Africa. Because of the difficulty in keeping chamaeleons in captivity, these beautiful reptiles die in large numbers. There are some who would like to see something done about it.

Our center has bred chamaeleons in the past, but it has had problems distributing information to others interested in breeding these delicate animals.

We need members, and if you would like to join, just write to the address printed below. For the moment there will be no fee.

You will receive a bi-annual journal, a newsletter every three months. The journal will contain articles from all over the world about old and new ideas in chamaeleon breeding. The newsletter will contain interesting bits of information, as well as announcements and ads.

The ideas offered here would be of great interest to anyone involved in reptile breeding.

PISTOIA MEMORIAL

On April 15, 1978, a plaque was installed in the Reptile House at the Columbus Zoo in fond memory of Louis Pistoia, for his lifelong contributions to the science of herpetology and his dedicated efforts in establishing the Columbus Zoo's Reptile Collection as one of the finest and largest in the United States. During his tenure at the Columbus Zoo, he designed the innovative Reptilia-Amphibia Hall which opened in 1968. In 1973, Mr. Pistoia and the Columbus Zoo received the distinguished Robert Bean Award from the American Association of Zoological Parks and Aquariums, specifically for breeding and raising Jamaican Boas.

NEW HERP REPRINT

Fossil Lizards of North America by Charles W. Gilmore, 1928. Reprinted with permission from the National Academy of Sciences, by the Riverside Museum Press (1978). This 50th anniversary edition features an introduction by Richard Estes, recapping advancements in paleoherpetology since 1928.

Riverside Museum Press, P. O. Box 547, Riverside, California 92501, U. S. A., $24.95.

NEW HERP HUSBANDRY BOOK

Bonath, Klaus. 1977. Narkose der Reptilien, Amphibien und Fische. Verlag Paul Parey. Berlin and Hamburg. 159 pp., 30 figures and 30 pages. This is part of the series: "Schriftenreihe Versuchstierkunde" No. 4. The paperbound price is DM 49- or about $25.00.

The book covers in quite detailed fashion the latest material on anaesthetics of lower vertebrates including dosages, methods of administration, etc.

Address of the publisher: Verlag Paul Parey, Lindestrasse 44-47, D-1000 Berlin 61, West Germany.

IGUANA INFO NEEDED

Matt Braunwalder (Finsterrutistrasse 5, 8134 Adliswil, Switzerland) is preparing a comprehensive article on captive maintenance of Iguana iguana for SALAMANDRA. He would appreciate receipt of reprints dealing with any aspect of their husbandry, ecology and reproduction, as well as data pertaining to these topics. The University of Zurich library is not complete enough to allow a thorough study. Material should be airmailed to eliminate loss.

HERPERVERTOLOGICAL REVIEW II

For those who said it couldn't be done. In spite of those who said it shouldn't be done. Herpervert. Rev. Vol. 0 no. 2 glooms on the horizon, and will grace your packets at the 1980 meeting of SSAR. So, those of you who were too chicken to contribute to 0 (1), or those of you villified in 0 (1) who seek revenge, or those of you just released from mental institutions, here's your big chance. CONTRIBUTE! Otherwise, Pisani will have to do the whole reeking thing himself, and y'all know what that means. Send your deprecations to George Pisani (address on inside front cover), who will cull the wheat from the chaff and save the latter.

EDWARD HARRISON TAYLOR

An Edward H. Taylor Memorial Fund for the aid of students in herpetology has been established at The University of Kansas Endowment Association, Lawrence, Kansas 66045. (An obituary will appear in the December issue of Herpetological Review.)

HERPETOLOGICAL
SKELETONS
SKULLS

Prepared for educational and display needs.

Over 1000 specimens in stock. From 2 in. tree frog to 7 ft. monitor lizard and 16 ft. python.

We welcome your requests and inquiries.

Current Literature

As of March, 1978, approximately 87 searchers are scanning 450 journals. Titles are published four times per year. Searchers are encouraged to submit titles for inclusion at three month intervals to assure approximately equal listings in HR.

Anyone publishing in a journal that is not widely distributed is invited to submit a complete citation or send a reprint to insure that the reference is published in Current Literature. Complete citations to obscure references are also welcome.

A new feature of Current Literature is the inclusion of senior author addresses. Although only a small portion of the citations have the addresses included in this issue, it is a goal to publish addresses for a majority of the citations for Current Literature in 1979.

Richard D. Worthington, Current Literature, Department of Biological Sciences, The University of Texas at El Paso, El Paso, Texas 79968.

EDITOR'S NOTE: With this issue of HR, we begin trial of a new format for Current Literature. HR 9(4) will use the same format, except that column separation will be increased. The editors would appreciate reader comments pro or con. The intent of Current Literature is to serve you, while remaining within certain cost limits. If this format gains user acceptance, we can increase the number of titles presented by 1/3 within our present budget.

Maintenance of Rattlesnakes in Captivity

by JAMES B. MURPHY and BARRY L. ARMSTRONG

Contains:

Basic requirements for maintaining rattlesnakes under optimal captive conditions

Extensive information on diseases, infections and treatments of captive rattlesnakes with direct reference to over 20 species

A thorough appendix of medical products for use in treating ailing rattlesnakes

An invaluable bibliography on rattlesnake diseases and treatments

A storehouse of information applicable to proper maintenance of all snakes in captivity

Howard K. Gloyd's

Rattlesnakes
Genera Sistrurus and Crotalus

WITH A NEW INTRODUCTION BY HOBART M. SMITH AND HERBERT S. HARRIS, JR.

About 320 pages including 31 plates of photographs; Index; 7 x 10 inches; Clothbound

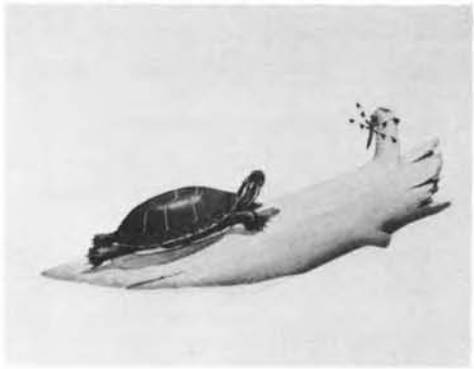
GLOYD'S monograph, "The Rattlesnakes, Genera *Sistrurus* and *Crotalus*, a Study in Zoogeography and Evolution," has been a standard reference since it was published in 1940 by The Chicago Academy of Sciences. Now long out-of-print, it is one of the most sought after of herpetological books because of its continuing utility. It includes an historical narrative about rattlesnakes, a taxonomic key, and detailed accounts of the 45 species and subspecies of rattlesnakes then recognized. These accounts contain for each form an extensive nomenclatural synonymy, a detailed description including scutellation and coloration, a section on distribution with map and list of specific localities, and a discussion of variation. There are 22 tables of data on geographic variation, 32 figures and maps in the text, and 31 plates containing, in part, 47 photographs of living rattlesnakes, plus an index.

The reprint also includes a new introductory essay by Hobart M. Smith and Herbert S. Harris, Jr., containing a biography of Howard K. Gloyd, a recounting of the production of his book, and an extensive table showing the current status of scientific names utilized in Gloyd's book.

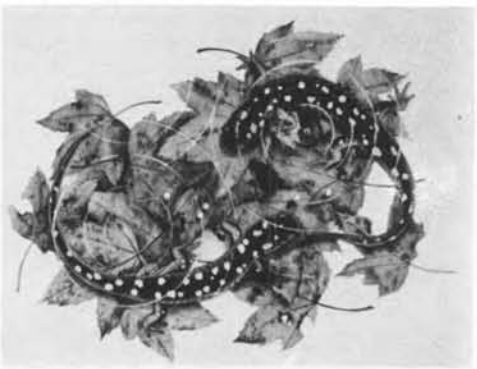
Prices and Ordering

SSAR members, if ordered *before November 1*	$15 clothbound
Institutions; Non-members; All orders received *after November 1*	$20 clothbound

Orders may be placed now; the book will be issued in December 1978. To take advantage of special pre-publication rates, SSAR members must send their orders *before November 1*. All orders should be sent to Dr. Douglas H. Taylor, Department of Zoology, Miami University, Oxford, Ohio 45056, USA. Please make checks payable to "SSAR"; receipt sent on request only. Prices include postage, world-wide.



A pricelist of other Society publications can be obtained from Dr. Taylor.



NATURAL HISTORY PRINTS
BY DAVID M. DENNIS

FOR THE FIRST TIME wildlife prints by David M. Dennis are being offered for public sale. These portraits are *full-color reproductions* of the original watercolor drawings, each printed on a sturdy paper stock measuring 20 by 24 inches and suitable for framing. Prints are *strictly limited to an edition of 500 copies, each of which the artist has numbered and signed individually.* Because of the relatively small size of the edition and the fact that this is the first offering of Mr. Dennis' work, these prints represent a sound investment as well as a visual delight. They would also be ideal for gifts.

Mr. Dennis is widely known to the scientific community as a wildlife artist specializing in watercolor portraits of lower vertebrates and insects. His self-taught artistry is complemented by his academic training in biology and his personal field experience with each of the animals he paints. Mr. Dennis earned his undergraduate degree in zoology from The Ohio State University in 1966 and since then he has held a succession of positions as biological illustrator at the Columbus Zoological Gardens, the University of Kansas Museum of Natural History and now at Ohio State. He has illustrated numerous biology textbooks including one which he co-authored, but is perhaps best known to vertebrate biologists for the exquisite series of watercolors published in *Hylid Frogs of Middle America* (The University of Kansas Press, 1970). Originals of Mr. Dennis' watercolors have been exhibited in art galleries and museums throughout the United States and also at numerous scientific meetings.

TO ORDER please use the form provided below:

_____

your name (please print)

_____

address *city* *state* *zip*

Please mark the appropriate boxes and fill in the last column.

☐ Plate 1: *Green Frog*, $25 each	$.
☐ Plate 2: *Painted Turtle*, $25 each	.
☐ Plate 3: *Spotted Salamanders*, $25 each	.
☐ Plate 4: *Hercules Beetle and Red Salamander*, $25 each	.
☐ Plates 1-4: *Set of all 4 plates* (if ordered together), $85	.
New York State residents, please add 7% sales tax	+ .
Packing, postage, insurance	+ 3.50
TOTAL REMITTANCE	$.

Make your check payable to BIOGRAPHICS. Prints are packed with care and shipped pre-paid and insured world-wide. Allow 4 weeks for delivery, longer overseas.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of Herpetological Review in 1967 (Corson Hirschfeld, Editor):

> "Herpetological Review incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the Review will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Now in its tenth year, Herpetological Review remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the Journal of Herpetology -- see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Authors are urged to write the editors before submitting feature-length articles. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles are desired. Submissions should be black-and-white, 8 X 10, glossy prints, and should be accompanied by a descriptive caption and exposure data. The name and address of the contributor should be taped or penciled on the back of each print. Please DO NOT send photographs before corresponding with the editors about them. Return of unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions can be supplied if desired. Contributors will receive ordering information prior to publication of their material. Herpetological Review will accept commercial advertising. Rates and copy information are available from the editors.

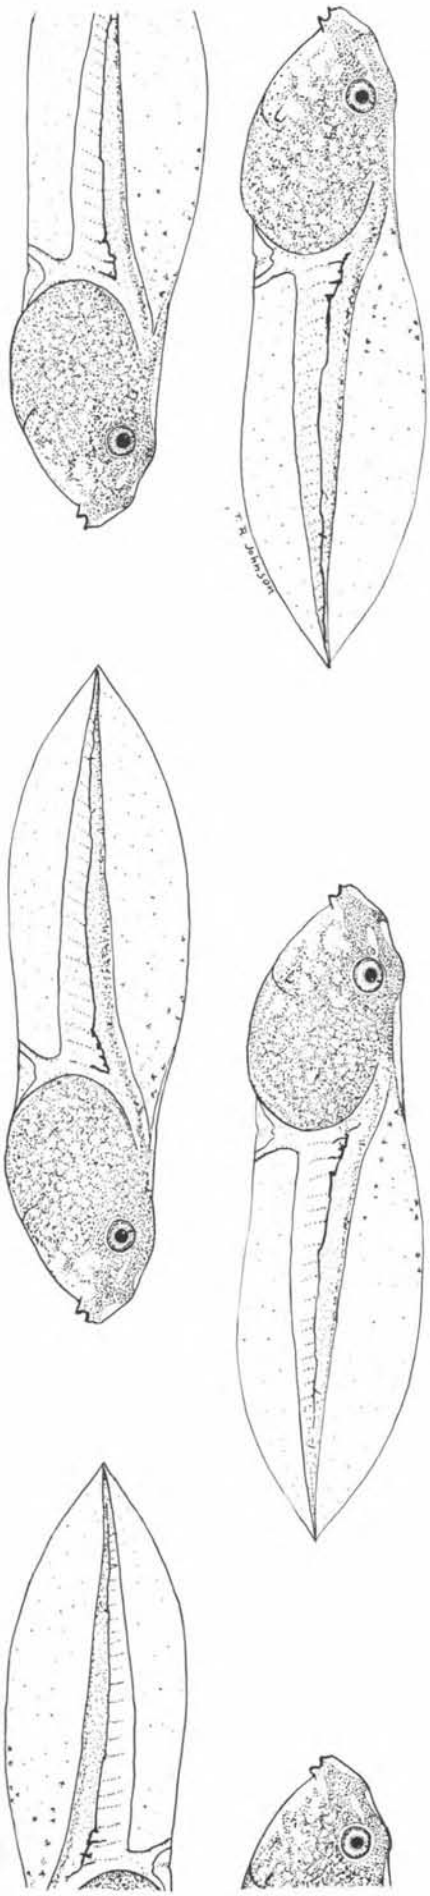
SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the Journal of Herpetology (four issues per year), Herpetological Review (four issues per year), Herpetological Circulars, and several Facsimile Reprints in Herpetology. Members may purchase other Society publications at reduced rates.

ANNUAL DUES



Student member	$10.00
Regular member	$12.00
Sustaining member	$20.00
Contributing member . . .	$25.00
Institutional	$20.00

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of the SSAR. For information about SSAR membership, write to:

Intra-Abdominal Retention of Eggs by the Soft-Shelled Turtle *Lissemys punctata punctata* (Bonnaterre) (Reptilia:Testudines:Trionychidae)

The tendency of turtles to retain eggs abdominally has been occasionally reported (Cagle, 1944; Cagle and Tihen, 1948; Risley, 1933). Though a natural event, such retention has been generally attributed to lack of suitable conditions for egg deposition. However, in one case, *Deirochelys reticularia*, retention of shelled eggs in the abdomen has been attributed to abraded oviducts (Cagle and Tihen, 1948).

A solitary case of intra-abdominal retention of eggs was observed by the authors in a mature female *Lissemys punctata punctata* among fifty or more that had been dissected by the junior author. The turtle was collected on 20 March 1976 from a shallow pond near Ranbirsingh Pora, 24 KM south of Jammu city. It weighed 1205 gm. Its carapace measured 214 mm in length and 202 mm in width. On dissection for routine gonadal studies on 23 March 1976, 4 full-size eggs with intact shells were found free in the abdominal cavity, two in each side. One of the left-side eggs had the shell partially mineralized. The oviducts in this specimen were conspicuously small and lacked differentiation into typical parts, the infundibulum, tubar, uterus and vagina. These reduced and stump-like oviducts looked like the combined uterine and vaginal regions of the normal oviducts. Neither contained any egg inside it. The right oviduct was 50 mm long and the left 80, whereas in a normal specimen of about the same size and weight, the length of the oviduct reaches more than 600 mm and is fully differentiated into the aforementioned regions.

In sections (Figs. 1 and 2), a strong histological differentiation was observed. The mucosal epithelium was very thin, lacked ciliary tracts and was backed up by the uterine glands. These glands were, however, less abundant than in the normal oviduct. Longitudinal folds characteristic of normal oviducts, were inconspicuous, although a thick loose connective tissue was seen to intervene between the glandular zone and the mucosa (Fig. 1). In normal oviducts, this tissue is comparatively thinner.

Normally, *L.p. punctata* oviposits from August through October, a period which corresponds to the post-monsoon months in Jammu. Thus, the presence of eggs in the month of March in this specimen is unseasonal and the conditions for their laying most unsuitable. While such a retention may well explain reports of unseasonal presence of eggs or the irregular deposition of eggs, as has been hinted by Cagle and Tihen (1948), it could as well be the reverse (late development and unfavorable season causing retention. --ed.). The latter possibility is higher and more reasonable.

Although intra-abdominal retention of eggs in the turtle *Deirochelys reticularia*, has been attributed to its abraded oviducts (Cagle and Tihen, 1948), in the present case wherein the oviducts were also deformed, a similar retention cannot be due to puncture or abrasion. The presence of shells implies a cranio-caudal passage of these eggs through normal oviducts. Either adverse seasonal conditions or lack of appropriate laying grounds must have led to the failure of this clutch of eggs to be deposited. The eggs thus seem to have reversed their normal passages, such reversed ovular movements being already on record (Risley, 1933), and as a result lodged in the abdominal cavity rather than be abandoned to adverse climatic conditions and lost.

The deformity in the oviducts in this turtle could also be an outcome of the reversed movement of the eggs, which in the region of the tubar have overcome the resistance offered by this narrowed section by rupturing the oviducts and falling free into the abdominal cavity. This explains the absence of characteristic ostium, infundibulum and tubar of these oviducts. This rupturing, though apparently more severe than that seen by Cagle *et al.* (1948), is the same basic cause of the *Deirochelys* and the *Lissemys* eggs being free in the abdominal cavity. Moreover, although abnormal, such retention of eggs is obviously unaccompanied by any lethal implications for the mother, but from a population standpoint, she would have been a liability as she would be then a consumer of resources who could not reproduce her species any longer due to massive oviducal damage.

ACKNOWLEDGMENTS

We are thankful to Professor Y.R. Malhotra, Head of the Department of Bio-Sciences, University of Jammu, for facilities to work. To the unknown reviewer, we owe our gratitude for drawing our attention to the implications of such damage and retention from a population standpoint.

Predation Upon Bats by Epicrates cenchris cenchris in Colombia

On 27 September 1976, while collecting bats during the day in El Parque Nacional Natural de la Macarena, Meta, Colombia, I observed a Brazilian rainbow boa, Epicrates cenchris cenchris, apparently foraging among a group of leaf-nosed bats (Phyllostomatidae) which were disturbed from their roost site along the rock ledges of a narrow cave located at the junction of Cano Nevera and the Rio Zanza (3° 10' N lat., 74° 5' W long.; alt. 600 m). When discovered, the boa was approximately 15 m from the cave entrance and 2 m above the cave floor in almost total darkness. The snake was captured, photographed, examined carefully, and then released. The specimen measured 1.15 m total length, and contained one "bat-shaped" prey item protruding against its sides. Palpation supported the suspicion that the prey was a bat, revealing forearm bones, body shape, and skull size all approximating the correct dimensions of the bats in the cave. Bats from the cave were collected and identified as a single species of short-tailed leaf-nosed bat, Carollia perspicillata (Pine 1972); several hundred individuals occupied the small cave. In all probability, and to my satisfaction, the evidence indicates the snake was preying upon this species of bat. A dead specimen of Epicrates cenchris cenchris was found on a nearby trail and collected for identification.

Other members of the Boidae have been reported to prey upon bats, including an African python (species not given), the Cuban boa, Epicrates angulifer, and the common boa constrictor, Boa constrictor imperator (Thomas 1974). This is the first account of Epicrates cenchris cenchris preying upon bats in the wild. Bat caves in the tropics offer excellent feeding areas for snakes, often containing large numbers of roosting bats and narrow ledges on which to hunt them.

My work in Colombia was supported by the Smithsonian-Peace Corps Environmental Program. I am grateful to Dr. Federico Medem, Director of the Instituto Roberto Franco, Universidad Nacional de Colombia, Villavicencio, Colombia for identifying the snake and encouraging me to write this note. I also thank fellow Peace Corps volunteers Tom Defler and Paul Gertler for assistance in the field.

An Albino Chelydra serpentina serpentina (Reptilia: Testudines: Chelydridae) From Ohio

Albino specimens of Chelydra serpentina serpentina have been reported twice before in the literature. Hensley (1959) reported two cases of albinism in this subspecies: a specimen from near Windsor (Ontario), Canada, and another specimen that was kept alive at The Childrens Nature Museum in Charlotte, North Carolina. Judd (1970) reported another albino Chelydra serpentina serpentina from southern Ontario, Canada.

Here, the authors wish to report another case of albinism in a Chelydra serpentina serpentina hatchling. The specimen (Figure 1), lacking all pigment and having pink eyes and a carapace length of twenty-eight millimeters, was collected near the town of Fairfield (Butler County), Ohio, in late March-early April 1975 (exact date unknown). It was given to one of the authors by a man who stated that he had found it floating down a small stream, in a lethargic condition.

The hatchling was kept alive for approximately six months and was fed a diet of shrimp and fish with vitamin and calcium supplements. While in captivity, algal growths appeared on its carapace, and were periodically scrubbed off (nonetheless, the preserved specimen still has some remaining algae adhering to its carapace). The turtle died of unknown causes in September of 1975.

The specimen has been placed in the collection of The Division of Reptiles and Amphibians of the National Museum of Natural History-Smithsonian Institution, USNM 203839.

Figure 1. Dorsal view of albino Chelydra serpentina serpentina hatchling. Dark blotches are algal growths.

Bullfrogs Preying on Cedar Waxwings

The senior author, accompanied by Francis Becker on 20 and 21 April 1971, visited the Don Crawford ranch about six miles north of Strawn, Palo Pinto County, Texas. One extremely common bird observed on this trip was the Cedar Waxwing (Bombycilla cedrorum), of which great numbers were noted coming to drink at the ranch's various stock ponds. On the 20th of April, over 1,000 birds were seen, and on the following day, an estimated 2,000 waxwings were present at the ponds. The water level in the ponds was very low, averaging about six to eight feet below normal due to a rather severe six-month drought. During this time, the weather conditions continued hot and dry with clouds prevailing.

On 20 April, waxwings came in large flocks (several hundred at a time) to the willow trees (Salix sp.) on the dam of one of the ponds. The birds swarmed down in a continuous stream to drink at the edge of the dam which was lined with stone. On several occasions, the birds were also seen on the mud at the edge of the pond. About a dozen large (14 to 16 inches extended length) bullfrogs (Rana catesbeiana) were spaced at intervals of four to five feet along the bank of the dam. Since some of the frogs appeared unusually fat, several of the larger ones were collected and their stomach contents examined. One stomach contained remains of two Cedar Waxwings, of which one was partly digested and the other appeared to have just been taken. A fresh waxwing was found in the second stomach.

On 21 April, several more large frogs were collected and three stomach contents examined. Each of these contained a Cedar Waxwing. A fourth

frog was observed sitting in the shallow water of a pond with a waxwing's tail feathers protruding from its mouth. All the birds presumably were swallowed head first as the heads appeared the most digested in the majority of cases. In addition, the frog stomachs held remains of unidentified beetles.

Although frogs were not seen capturing Cedar Waxwings, this predation seemingly was influenced by the local conditions. Cedar Waxwings commonly frequent the area since much Ashe Juniper (Juniperus ashei) is found in Palo Pinto County. Pulich has seen over 5,000 waxwings in this area in a single day in previous winter periods. The birds feed upon the berries produced by juniper. Being voracious feeders they gorge themselves and then fly to water to drink, a feeding habit well evidenced by the tell-tale signs of red-washed berry droppings around all the dams and edges of the ponds. This, coupled with the birds' flocking habits, provided the proper environment for frogs to readily capture Cedar Waxwings. This predation was not unique to just one pond, as remains of Cedar Waxwings were found in the stomachs of frogs collected from three different ponds on the ranch.

Carpenter and Morrison (Bios 44: 188-193, 1973) found two Cedar Waxwings in stomachs of two of the 124 bullfrogs sampled during a study which was conducted in the fall of 1970 and the spring of 1971 near Stephenville, Erath County, less than 40 miles away from the Crawford ranch. They concluded "...that the bullfrog is an opportunist and will eat anything it can catch and swallow..."

Thus, the drought conditions prevailing locally during this time certainly made the Cedar Waxwing a vulnerable food item.

TIMOTHY GOLLOB, 2926 E. Ledbetter Drive, Dallas, Texas 75216 and WARREN PULICH, SR., University of Dallas, Irving, Texas 75061.

An Albinistic Sagebrush Lizard, Sceloporus graciosus

On August 30, 1975, an immature albino specimen of Sceloporus graciosus was collected at a residence in Weaverville, Trinity County, California. At the time of capture, the specimen was basking on a cement block which measured 20.2 x 40.4 cm. The lizard lacked melanic pigment, and the eyes were totally pink. The snout-vent length was 24 mm, the tail 15 mm. The albino appeared to be less active than normally pigmented ones brought into the laboratory at the same time. When mealworms of various sizes were offered the albino, it made no attempt to feed. Normal lizards fed actively. This behavior compares to that observed by Eells (1964) in an immature albinistic specimen of Taricha torosa, which refused food while normal salamanders actively fed under the same conditions. Childs (1953), in a study of predation on albino and normal spadefoot toads, Scaphiopus hammondi, reported that subsequent to metamorphosis the albinos became shriveled, lethargic, and died, while numerous normally pigmented toads were alive and healthy under the same conditions. This suggests that the albino animals may not have been feeding as actively as the normal ones.

The specimen is presently located in the Conservation Department, Trinity High School, Weaverville, California 96093.

A Report on the Restoration of the Preserved Amphibian and Reptile Collection of the Toledo Zoological Society

The Toledo Museum of Science and Health is housed on the grounds of the Toledo Zoo, and is operated by the Toledo Zoological Society. The preserved amphibian and reptile collection housed in the museum building was collected and curated under the guidance of Dr. Roger Conant during the period when he was curator of reptiles at the zoo. The bulk of the material was collected during the years 1930 through 1934. Collections were made preparatory to Conant's comprehensive work on the reptiles of Ohio, published in 1938. Most of the specimens of reptiles in the collection represent important locality records cited in Conant's work, and hence the collection is of considerable value despite its relatively small size (ca. 2800 specimens).

My involvement with the collection began May 1977 while visiting the zoo. At that time I examined the collection, which was in a deteriorated condition, and was told that the zoo was desirous of having it restored. I later sent a proposal to the director of the zoo offering to restore the collection, and funding was obtained to employ me for such a project during the month of November 1977.

The collection room had been established approximately six years before my arrival, and at that time some effort had been made to improve the condition of the collection. This consisted primarily of cleaning the entire room. Until that time, the room had apparently not been opened since the late 1930's.

Specimens in the collection are stored in glass jars with heavy wire closures and rubber seals, each specimen having an attached metal tag bearing a catalog number. Data for each specimen is recorded on a label attached to the outside of each jar. Unfortunately, time did not permit me to make proper labels for the inside of each jar. Specimens are catalogued by accession number, with the amphibians and reptiles catalogued separately. There are no indices to the collection.

The restoration procedure consisted of cleaning each jar, replacing the preservative and rubber seal, and making certain that each specimen had the catalog number securely attached. In addition, the collection was arranged on the shelves in precise taxonomic order and necessary taxonomic corrections were made. Fortunately, the original curation of the collection had

been well done, and the majority of the specimens were in good condition.

Approximately 3275 specimens were listed in the collection catalog, of which 459 specimens (14%) were missing. The remaining 2816 specimens consist of ca. 75% reptiles and 25% amphibians. Of the reptiles, largest holdings are of the genera Chrysemys, Natrix, and Thamnophis, with these genera comprising 44% of the total reptile content of the collection. The largest amphibian holdings are of the genera Desmognathus, Plethodon, and Rana, and comprise 58% of the total amphibian content. The taxonomic content of the collection is presented in Table 1.

Geographically, 72.5% of the collection is from Ohio, with the remainder coming from various other states as follows: Tennessee, 5.1%; Oklahoma, 1.5%; North Carolina, 1.2%; and Michigan, 1%. The remaining 5% come from the states of Arizona, Colorado, Illinois, Indiana, Kentucky, Louisiana, Massachusetts, Minnesota, Montana, New Jersey, New York, South Carolina, Utah, Virginia, and Washington.

Unfortunately, several problems were encountered during the restoration process (these arising primarily from a shortage of time and supplies), and I was unable to do as thorough a job as I had originally planned. I preserved 62% of the collection in 70% ethyl alcohol, after which the supply was exhausted, and I was forced to preserve most of the remaining specimens in 10% buffered formalin. Due to the lack of time and supplies, I was unable to finish the restoration of specimens of Thamnophis, as well as several of the amphibian genera.

The museum has adopted a policy whereby no specimens are to be sent out on loan. However, researchers ar welcome to come to the museum to examine specimens. Inquiries concerning the collection should be addressed to Mr. Joseph Beckler, Curator, Museum of Science and Health, The Toledo Zoo, 2700 Broadway, Toledo, Ohio 43609.

ACKNOWLEDGMENTS

I wish to thank the following officials of the Toledo Zoo for their assistance: Mr. Joseph Beckler, Museum Curator; Mr. William Dennler, Curator of Reptiles; Mr. Martin Jan, Museum Coordinator; and Mr. Phillip Skeldon, Executive Director. I would also like to thank my part-time student assistants, Ms. Nancy Bennett and Ms. Kelly Gage.

Book Reviews

THE AMPHIBIANS OF MISSOURI, by Tom R. Johnson, 1977. University of Kansas Museum of Natural History, Public Education Series No. 6. viii + 134 pp., 67 figures, 42 maps, $5.00 Paperback.

This attractive and carefully prepared little book is an excellent introduction to the amphibians of a state for which no other modern treatment exists. It aims at a general audience while retaining features of value to professional students of the Amphibia.

The meat of the book consists of Family Accounts (12 of them) that place the relationships and ranges of Missouri forms in a broader, world-wide context; and individual Species Accounts (40 of them) that includes an excellent black and white photograph (about 4 inches wide), a Description (coloration, sexual differences, size range, other distinctive features that aid identification), Habits and Habitat, Breeding, Subspecies (geographic variation in Missouri) when appropriate, Remarks, and Missouri Distribution of species and subspecies with a small, but quite suitable, map showing presumed range (shading) and verified localities (county dots). Particular effort was made to be sure the nomenclature and range maps accurately summarized current knowledge. Also included are a Table of Contents (by common and zoological names), and Introduction (containing a brief explanation of classification and zoological nomenclature and descriptions of physiographic provinces in Missouri related to geographic distributions of certain species), a Checklist of Missouri Amphibians (by common and zoological names, arranged by family), illustrated taxonomic Keys to the species identification of adult specimens (should also work for most postmetamorphic juveniles as well), a discussion of possible occurrence of 6 additional species in the state, a short Glossary, a good Bibliography (175 entries), and a useful Index to zoological (by generic and specific epithets) and common names (by all permutations: e.g., eastern gray treefrog is listed under "eastern," "gray," and "treefrog."

Johnson's considerable skill in drawing and photography have been used to excellent advantage. For anyone interested in the identification, distribution, and natural history of amphibians in Missouri, this book is a must.

RONALD A. BRANDON, Department of Zoology, Southern Illinois University at Carbondale, Carbondale, Illinois 62901.

THE AMPHIBIANS OF MISSOURI. By Tom R. Johnson with illustrations by the author. The University of Kansas Publications, Museum of Natural History. ix + 134 pp.

The task of familiarizing and educating a public which is largely ignorant and often afraid of herptiles becomes a larger and more important challenge for professional herpetologists as natural environments and their inhabitants continue to be abused. What protective legislation exists is frequently useless unless the general public as well as the professional can recognize and respect protected wildlife.

At first perusal, Tom Johnson's Amphibians of Missouri may appear as a fieldbook outsized by Conant's A Field Guide to Reptiles and Amphibians of Eastern and Central North America and preceded in format and general purpose by Collins's Amphibians and Reptiles in Kansas. With such comprehensive materials already available, why publish a more limited, localized book?

In a time when demands for relevance sound more and more like the battle cry of the decade, a book which focuses information in a meaningful way for people in a particular region plays an important role in public education. People may be more likely to read about amphibians in their own state than about amphibians and reptiles in a larger or different region. Once drawn to the book, they will not be disappointed, for Johnson has taken great care to make his book both readable and enjoyable. He avoids technical terms or defines them in a glossary and clearly explains basic concepts and presents background materials in the introduction to the book. Individual species accounts include a description, notes on habits and habitats, breeding, additional remarks, and information about the animal's Missouri distribution. His work is thorough and should satisfy most professional readers without overpowering amateurs and the general public.

One feature which makes this book especially delightful is that its author is an artist as well as a scientist. Johnson's sketches and photographs illustrate the text beautifully and one can only hope that sales of the book will soon justify a second edition in color.

BARBARA P. PASCHKE, Office of Institutional Research and Planning, University of Kansas, Lawrence, Kansas 66045.

A BIOGEOGRAPHICAL ANAYSIS OF THE CHIHUAHUAN DESERT THROUGH ITS HERPETOFAUNA by David J. Morafka, 1977. Biogeographica, Volume 9, viii + 320 pp. 95 Dutch Guilders (about $39).

Morafka's published version of his Ph.D. dissertation sets out to make the study of biogeography a rigorous analytical science. He proposes an explicit methodology for the study of biogeography in which the data are not combined with the analysis, thus avoiding the teleology inherent in many biogeographical analyses. For the system under study, Morafka attempts further rigor of analysis by proposing models which are then tested. The success of this approach will be evaluated after consideration of certain criticisms.

There are 10 pages of explanations for explicit taxonomic decisions on the generic or species level for 32 taxa. The following comments are representative, not exhaustive.

A biogeographical analysis is not the place to offhandedly revise the genus Eleutherodactylus. Morafka offers his opinion on this topic with respect to Hylactophryne. Acceptance of Hylactophryne would not change the analysis as presented and would have been consistent with current taxonomic usage.

On page 72, Morafka devotes a paragraph to arguments why Callisaurus, Cophosaurus, Holbrookia and Uma all should be considered as congeneric. I assumed that they would be so treated in the rest of the book. Not so. One is left wondering why the topic was raised.

There are three instances involving taxonomic problems that are not dealt with in the section set aside for that purpose. (1) As a footnote on page 80, Cnemidophorus dixoni is synonymized with C. tesselatus. Why was this action not explained on page 73 where C. dixoni is mentioned as a taxonomic problem? (2) Throughout the analysis, Sceloporus cautus plays an analytic role as it is endemic to the Chihuahuan desert. On page 199 in the discussion section on the historical biogeography of the Chihuahuan herpetofauna, S. cautus is essentially synonymized with S. undulatus. Why is the synonymy mentioned in the discussion? Unfortunately, an answer comes all too readily to mind. In the analysis section, S. cautus supported the distinctiveness of the Chihuahuan herpetofauna. On page 199, however, in the particular subregion of the Chihuahuan desert that S. cautus is endemic to, the Saladan Desert, Morafka argues against the Saladan as a desert glacial refugium. This time, endemics in the Saladan Desert would not support the argument and S. cautus is the only endemic in the Saladan Desert. (3) The one taxon that needed discussion, if any

did, is Rana pipiens. Morafka makes no mention of the taxonomic status of this form in his study area and uses the name R. pipiens throughout. Of the two or three species of this complex in or bordering the area under study, none is pipiens!

I found the book difficult to read because of the author's style of writing. It has a pomposity usually found only in dissertations and the pages of the American Naturalist or recently, Systematic Zoology. While the Guru can enlighten the flock in the short papers of the Naturalist, or a graduate student's excesses overlooked in a dissertation, the same style irritates in book length format.

Apparently, Morafka did not rewrite his dissertation for publication, but added new information by liberal use of footnotes. The most serious problem this approach caused is on page 179, where the paleogeographical discussion in the text is stated to be incorrect in a footnote based on the most recent evidence. For the high price asked of this book, I think the author should have revised the text throughout to incorporate the changes required by the 3-year interval from dissertation to submission of the manuscript for publication.

The literature citations I am familiar with are poorly handled. Morafka cites an article by Heyer and Savage, reversing the order of the authors as published and reversing the initials of Heyer. McDiarmid fares even worse. His name is variously spelled McDiarmid and MacDiarmid. The dates cited for McDiarmid's master's thesis are given as 1964 (pp. 168, 179) and 1965 (p. 182) in the text, while the literature section cites the date (correctly) as 1966. As the only two papers I am familiar with before reading Morafka's book have errors associated with them, I have not cared to check any other citations for fear that the rest of the literature is equally poorly treated.

The production of the volume itself has detractions. There are enough typographical errors or production errors to be distracting to the reader (including a typo in the title on the title page). The most serious error is apparently where a press-on letter fell off Map 6, page 122, where the number 5 indicating the Tamaulipan Province is absent from the map. The most frustrating production problem is the quality of the maps. Maps are the heart of any biogeographical analysis and the quality of reproduction of the maps in the two copies of the book I have seen is plainly poor. The central map in terms of methodology, analysis and interpretation is Map 2, page 62, the base map of the Chihuahuan desert. Desert is supposed to be clear, non-desert stippled. Those distinctions are not visible in the figure.

The criticisms levelled here may appear harsh. Perhaps that is because if a study professes to be rigorous, I expect rigor throughout, including attention to details. What I find in this study is a pretension of rigor overlying recurrent sloppiness. That irritates me. I distrust the validity of the rigorous analysis because of the sloppiness of presentation.

If the pretentiousness of approach and sloppiness of presentation are overlooked, the basic biogeographical synthesis is credible. The study is indeed a synthesis which provides a better understanding of the Chihuahuan desert. Morafka examined the specimens himself; he constructed the range maps; he defined the area under study on the basis of criteria meaningful to the herpetofauna, not on the basis of political boundaries; he synthesized ecological parameters with the biogeographic construct. In these terms, the study is to be commended; many biogeographic studies lack most of these qualities.

The study stands as an eminently successful dissertation. We should have been spared the foibles acceptable in a dissertation in the published version, however. In terms of dollars, buy the book only if you are specifically interested in the herpetofaunal biogeography of the Chihuahuan desert; borrow it for any other interests.

RON HEYER, Amphibians and Reptiles, Smithsonian Institution, Washington, D.C. 20560, U.S.A.

Hemidactylus garnoti (Indo-Pacific Gecko). Female with 2 eggs; note the regenerated tail. This specimen was collected on a store in Hobe Sound, Martin County, Florida. It appears that this population was introduced by a landscaping outlet located next to the collection site. The female was captured 13 Nov. 1977 and laid 2 eggs 25 Nov. 1977. This species is triploid and parathenogenetic. Photograph by Robert Parelius. Specimen collected and photograph submitted by Steven Meyers.

Legislative Alert

Final Rulemaking Actions

Drymarchon corais couperi (eastern indigo snake) has been listed as Threatened in a final rulemaking issued by the U.S. Fish and Wildlife Service (effective 3 March 1978).

Parts of two southeastern Texas counties (Bastrap and Burleson) have been designated as Critical Habitat for the Endangered Bufo houstonensis (Houston toad) in another final rulemaking (effective 3 March 1978). In addition, the U.S. Fish and Wildlife Service is currently funding a status survey of the toad and its habitat needs in Harris County, Texas through the University of Houston.

In yet another final rulemaking (effective 6 March 1978) it was determined that Epicrates monensis monensis (Mona boa) and Cyclura stejnegeri (Mona ground iguana) are Threatened species and that their range--Mona Island, part of the Commonwealth of Puerto Rico--should be designated as Critical Habitat. Unique to Mona Island, the two reptiles are threatened by possible habitat modification and the presence of competitive and predatory feral animals.

Proposed Regulations

The U.S. Fish and Wildlife Service announced (F.R. Vol. 43, No. 76--Wednesday, April 19, 1978), a proposal to review the status of 16 species of herps on the U.S. Endangered List (see list below). These forms were placed on the Endangered Species List as a result of their presence in Appendix I of the Convention on International Trade in Endangered Species of Wild Fauna and Flora. This review will provide information upon which a determination can be made as to whether any or all of these species should be reclassified as Threatened or entirely removed from classification under the Endangered Species Act. Comments should be submitted no later than 18 June 1978 (see address in next paragraph).

Critical Habitat has been proposed for Dermochelys coriacea (leatherback sea turtle) in the U.S. Virgin Islands (F.R. Vol. 43, No. 57--Thursday, 23 March 1978). Although the leatherback has been a listed Endangered species since 1970, critical habitat has not been determined. This proposal would make the Sandy Point Beach area on the western end of the island of St. Croix subject to full protection under Section 7 of the Endangered Species Act of 1973. Public comments close 22 May 1978. Please

submit comments to: Director, Office of Endangered Species, U.S. Fish and Wildlife Service, Department of the Interior, Washington, D.C. 20240.

In response to a request by the Environmental Defense Fund, the public comment period on the proposed regulations to list the green, loggerhead, and Pacific ridley sea turtles as Threatened and to prescribe certain protective provisions, had been extended until 17 April 1978 by the National Marine Fisheries Service (F.R. Vol. 43, No. 59--Monday, 27 March 1978).

State News

On 7 April 1978, Georgia State Game and Fish Officials proposed a review of the status of the American alligator (Alligator mississippiensis) which may result in the removal of the species from that state's Protected Species list. In addition, Georgia officials proposed a review of the status of the gopher tortoise (Gopherus polyphemus) which would place the tortoise on the state's Protected Species list as an "Unusual species"--meaning the tortoise would receive complete protection under Georgia's Endangered Wildlife Act of 1973.

Comments on these two proposed actions are being actively solicited from the public; send your comments to: Ron Odom, Game and Fish Division, P.O. Box 119, Route 2, Social Circle, Georgia 30279, or by phone to 404/557-2532.

THOMAS J. BERGER, Museum of Natural History, The University of Kansas, Lawrence, Kansas 66045.

As noted in the Federal Register (42(229): 60743-60745), the Fish and Wildlife Service announced that the Atlantic salt marsh snake (Nerodia fasciata taeniata) is a Threatened species. This action makes the protection provided by the Endangered Species Act of 1973 available to this unique species. Determination of Critical Habitat has not yet been made.

Herpetologists and the Pan American Convention

On October 12, 1940, Secretary of State Cordell Hull signed the Convention on Nature Protection and Wild Life Preservation in the Western Hemisphere on behalf of the United States. This little known treaty has been ratified by most member countries in the Organization of American States. However, the implementation of the provisions of the Convention has been spotty at best and often ignored. This situation may soon change as the 17 member states review their international treaty obligations as a point of national pride and responsibility. Indeed, the United States is also reviewing this treaty as a prelude to active implementation and participation in its provisions. Executive Order 11911 of April 13, 1976, gave the Secretary of the Interior the responsibility for carrying out its provisions and in his environmental message of May 23, 1977, President Jimmy Carter proposed implementation now through the Organization of American States and offered to host an inter-American conference (possibly in 1979).

Most herpetologists have never heard of the Pan American or Western Hemisphere Convention, as it is called. Yet, with the increasing recognition that it is receiving in some Latin American countries, it would seem desirable to call attention to and highlight the main provisions of the Convention. Although a broad range of regulations are called for, each country so far has provided protection and restrictions according to its own established or newly enacted legislation. At present, species listed on the Annex to the Convention receive no specific legal protection in the United States, nor have regulations regarding permit procedures, if required in light of already existing procedures, been outlined for importation or exportation.

The main purposes of the Pan American Convention are to: 1) identify and preserve all species and genera of native flora and fauna in sufficient numbers over an area extensive enough to prevent their extinction, 2) protect and preserve areas with "scenery of extraordinary beauty, unusual and striking geologic formations, regions and natural objects of aesthetic, historic or scientific value, and areas characterized by primitive conditions...." and 3) provide a means "to effectuate the foregoing purposes...."

Article I of the Convention deals with definitions of national parks, national reserves, nature monuments, strict wilderness areas, and migratory birds. An important provision of this Article is that it allows a nature monument to be set aside for a single species. Article II requires member countries to explore the possibility of establishing national parks and reserves, nature monuments, and strict wilderness reserves, and to establish such areas as soon as possible. Article III states that contracting governments shall not alter park boundaries and that the resources of set-aside natural parks shall not be subject to exploitation for commercial profit. Hunting, killing, capturing, and destruction of native fauna and flora is prohibited except under direction of park authorities or for "duly authorized scientific investigations." It also stipulates that public recreational and educational facilities be provided. Article IV involves similar regulations for strict wilderness reserves.

Article V of the Pan American Convention requires member countries to enact laws for the protection of natural areas and their fauna and flora. Provisions for collection of specimens of fauna and flora for scientific study and investigations are specifically called for. In addition, this Article states that member countries should enact legislation designed to protect scenery and geologic features. Article VI calls for inter-American cooperation while Article VII deals solely with migratory birds.

Article VIII is probably the main area of concern to those involved in research in herpetology because it involves the protection of individual species (Annex to the Convention). This Article is reprinted in its entirety.

Article VIII

"The protection of the species mentioned in the Annex to the present Convention is declared to be of special urgency and importance. Species included therein shall be protected as completely as possible, and their hunting, killing, capturing, or taking, shall be allowed only with the permission of the appropriate government authorities in the country. Such permission shall be granted only under special circumstances, in order to further scientific purposes, or when essential for the administration of the area in which the animal or plant is found."

A list of amphibians and reptiles on the Annex to the Convention by O.A.S. member countries is provided in Table 1. It might be noticed that there is repetition in the list; some individual species are listed at the same time an entire genus or family is listed. This is because there have been several lists to the Annex published by various countries, and it is not clear whether the countries meant later species lists to supercede previous lists or merely to add to that country's original list.

Article IX states that member countries should take whatever measures necessary to control and regulate the importation, exportation, and transit of protected fauna and flora. Measures which might be taken to implement this Article include the issuing of certificates authorizing exportation or transit of protected species and the prohibition against importation of any species unless accompanied by a certificate establishing that the species was lawfully taken within the country of origin. Articles X,

XI, and XII govern the internal workings of the Convention (effective dates, membership, procedural matters).

It is not known at present how the U.S. will implement the Convention, nor which governmental agency would have responsibility for overseeing the provisions of the Convention. As such, the impact of the Pan American Convention on herpetologists is open to question. Should, however, the Convention be actively enforced by the United States, it would be hoped that all segments of the scientific community be consulted prior to implementation to insure that the best interests of the species involved be considered.

NEW HERP BOOK

"How Reptiles and Amphibians Live" by Arthur C. Echernacht. Elseiver-Phaidon, Mayfield House, 256 Banbury Road, Oxford, OX2, 7DH, England. 142 pages. 130 plates (125 in color). $8.75. (No U. S. distributor listed.) An excellent book with many fine color photographs. Highly recommended as a companion volume to the Time-Life series and Peterson Field Guides.

SALVADOR TO MADRID

Alfredo Salvador, formerly Resident Museum Specialist at Carnegie Museum of Natural History, has returned to Spain and taken a position in the Departamento de Zoologia, Facultad de Ciencias, Universidad Autonoma de Madrid, Cantoblanco, Madrid, Spain. He would appreciate continued exchange of reprints with American colleagues.

NEW RECORDING OF FROG CALLS

The Florida State Museum announces the availability of a new phonograph record on Florida frogs. It presents recordings of all commonly heard frogs and toads in Florida and is narrated by Linda Becker. $4.00. Order from: Florida State Museum, University of Florida, Gainesville, Florida 32611.

Herpetological Husbandry

Chemosensory Searching for Wounded Prey by Rattlesnakes is Released by Striking: A Replication Report

It has been demonstrated that chemosensory processes mediated by the vomeronasal system are most important for directing exploratory and predatory behaviors in natricine snakes (see Burghardt, 1970, for a review of the literature). (1) Presentation of a cotton swab saturated with odoriferous prey substances has been shown to activate food-seeking (e.g., orienting, tongue flicking) and attack responses in neonatal and adult garter snakes (genus Thamnophis), indicating that visual cues are probably unnecessary for the release of either appetitive or consummatory behaviors (Burghardt, 1969). Under some conditions, rattlesnakes are also able to detect potential prey by odors alone (Cowlers and Phelan, 1958), but visual cues arising from prey (esp. movement) have been found to be most important for the release of striking in both rattlesnake genera (Taylor, 1976). Consequently, the vomeronasal system appears to be of little significance during the initial phases of rattlesnake predation (orientation, approach, and strike). In fact, Chiszar and Radcliffe (1976) showed that, prior to striking, rattlesnakes emitted few tongue-flicks, whereas after striking, tongue-flick frequency increased significantly and was sustained at elevated rates until the commencement of swallowing. It was, therefore, hypothesized that chemical cues are not required until after the rattlesnake strikes prey, and that some aspect(s) of striking (sudden input of odor cues directly into Jacobson's organs, proprioception, etc.) activates the tongue-flick system. This chemosensory process then aids the rattlesnake in trailing its prey which might have wandered several meters away before dying (see also Baumann, 1927, 1928 and Dullemeijer, 1961).

Even though Chiszar and Radcliffe suggested that striking prey is the important factor in the activation of chemosensory searching in rattlesnakes, their study did not, in fact, demonstrate this because important controls were lacking in the experimental design. Specifically, no observations were made of hungry snakes which saw prey but did not have the opportunity to strike. If such a snake also exhibited a high rate of tongue flicking, then it would clearly be inappropriate to conclude that striking was the causative factor for activation of chemosensory searching. Accordingly, Chiszar, Radcliffe and Scudder (in press) exposed rattlesnakes to two conditions: (1) snakes saw, smelled and detected thermal cues arising from a mouse held just out of striking range for two seconds, and (2) same as condition 1 except that the snakes were allowed to strike the mouse at the end of two seconds. All mice were removed after the presentation period and all tongue flicks were recorded during the next 10 minutes. Only snakes in the second condition exhibited a sustained high rate of tongue flicking in the post-presentation period. Hence, striking was in fact necesary to activate chemosensory searching. In addition, once the rattlesnakes began to flick their tongues at a high rate, they ignored additional live mice (Chiszar, et al., Exp. 2). It was concluded that a successful strike (i.e., one which envenomates prey) accomplished two things: (1) it induced chemosensory searching and (2) it induced an inhibition against further strikes. Experiment I of the present report provides a replication of the strike-induced chemosensory searching phenomenon (SICS), and Experiment II provides a replication of the strike-induced inhibition of striking phenomenon (SIIS).

EXPERIMENT I

Subjects and Maintenance Conditions

Five rattlesnakes (Crotalus enyo enyo), which had been in captivity for six months, were observed in this experiment. All snakes were individually maintained in glass terraria (50 x 27.5 x 30 cm) kept at 26-28°C during the light period (0800-2200) and 22-24°C during the dark period. Each animal was fed one to three live adult mice every other week. The present observations were made just prior to a regular feeding session.

Procedure

The subjects were randomly divided into two groups: control (n=2) and experimental (n=3). Each snake was observed for five minutes prior to the presentation of a live mouse. The number of tongue flicks during this period was regarded as the baseline rate. Following the baseline period, a live mouse was lowered with forceps into the cage to allow the snake a brief period of inspection during which the mouse was held just out of striking range. Snakes of the control group were permitted to inspect the mouse for two seconds before the rodent was removed from the cage. Snakes of the experimental group were allotted equal time for inspection before being given an opportunity to strike the mouse; in every case, the mouse was struck immediately and was then removed from the cage. After presentation of the mouse, the number of tongue flicks was continuously recorded for a five minute period. These records were made with the aid of a hand-held, push button counter.

Results and Discussion

Figure 1 plots the mean number of tongue flicks as a function of minutes for the control (no strike) and experimental (strike) groups. Analysis of variance revealed a significant Group main effect ($F=27.6$, $df=1/3$, $p < .05$), indicating that striking increased tongue flicking above the rate seen in the control group. The significant Group x Period interaction ($F=16.8$, $df=1/3$, $p < .05$) indicates that the difference in tongue-flick frequency between the baseline period and the post-presentation period for the control group was not appreciable, whereas the experimental group displayed a large increase.

These data replicate our previous SICS finding. Visual, olfactory, and thermal cues arising from potential rodent prey are of little importance in activating chemosensory searching in rattlesnakes; it is the occurrence of the strike which initiates chemosensory searching. Of course, we restrict this conclusion to non-starved, well-acclimated captive rattlesnakes; whether or not a similar phenomenon occurs under natural

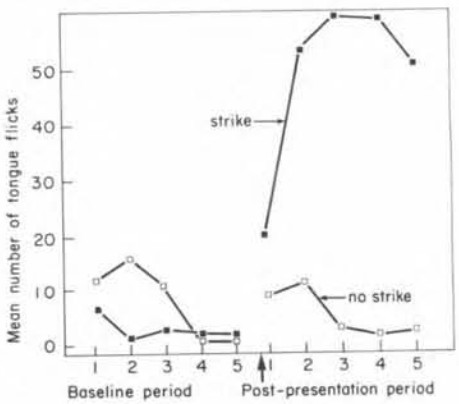

Figure 1. Mean number of tongue flicks during 5 minute baseline period and 5 minute post-presentation period for the control (no strike) and experimental (strike) groups. Subjects were five Crotalus enyo enyo. The numerical differences between groups during the baseline period were not statistically significant; the numerical differences during the post-presentation period were highly significant, especially between minutes 2-5.

conditions remains an empirical question.

EXPERIMENT II

Subjects

Twenty-three rattlesnakes (6 Crotalus viridis, 2 C. durissus, 2 C. vegrandis, 2 C. lepidus, 1 C. molossus, 1 C. atrox, 1 C. willardi, 1 C.catalinensis, 1 C. polystictus, and 6 Sistrurus catenatus) were subjects. All snakes had been in captivity for at least ten months and were maintained exactly as described in Experiment I. All of the present observations were made just prior to regularly scheduled feeding sessions.

Procedure

During each observation, two measures of attack latency were recorded. The first measure represented the time that elapsed from introduction of a live mouse to the time of the strike. The second measure was the latency to strike a second live mouse. For 16 snakes (Group A), the second mouse was introduced immediately after the first one was struck. For 7 snakes (Group B), the second mouse was introduced immediately after the first mouse was swallowed. Subjects were allowed a maximum of 300 seconds to strike any given mouse. If a snake did not strike during this period, the trial was terminated and a scale of 300 seconds was assigned. Successively presented mice were of similar size and color; all mice were from the same inbred strain (DBA) obtained from the Institute of Behavioral Genetics, University of Colorado.

Results and Discussion

Figure 2 shows the mean latencies for rattlesnakes to strike both the first and second mouse. The latency for rattlesnakes to strike the first mouse was always below 50 seconds and was usually less than 10 seconds. The latency of the second strike was considerably longer if the second mouse was introduced directly after the first strike (Figure 2a). A paired t-test comparing the latencies shown in Figure 2a was significant ($t = 11.52$, $df = 15$, $p < .01$). If the second mouse was introduced after the first mouse was swallowed (Figure 2b), the second strike latency was not different from the first ($t = 0.36$, $df = 6$, $p > .05$). For Group A, only 38% of the second-mouse presentations resulted in strikes within 300 seconds, whereas in Group B 100% of the second mice were struck ($\chi^2 = 7.4$, $df = 1$, $p < .05$).

The performance of Group A replicates the SISS phenomenon. These data strongly suggest that striking imposes a temporary inhibition on further striking of other prey that may be present.(2) The existence of this strike inhibition may help to focus the snake's attention on chemical cues for trailing, location, and ingestion of prey which has already been struck. The performance of Group B suggests that SIIS may be disinhibited by ingestion. However, the time that elapses during the ingestion of the prey might also allow for dissipation of the strike-induced inhibitory effect. Since approximately five minutes were required by Group B snakes to swallow their mice, it is possible that this temporal factor rather than ingestion is the critical variable in SIIS disinhibition.

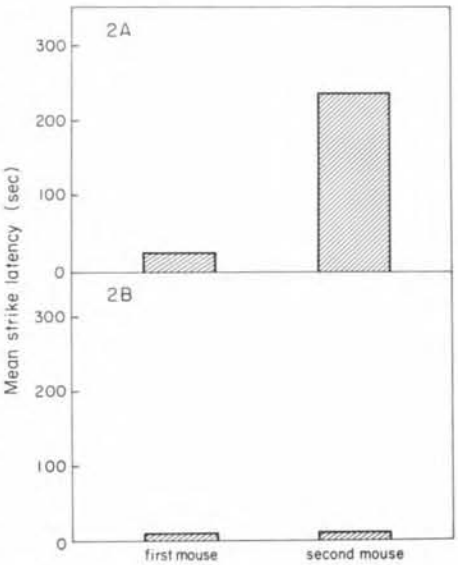

Figure 2. Mean latency to strike successively presented rodent prey. In 2A (16 snakes), the second mouse was introduced directly after the first was struck. In 2B (7 snakes), the second mouse was introduced directly after the first was swallowed (i.e., approximately 5 minutes after the first mouse was struck).

To discriminate between the effects of ingestion and passage of time on the disinhibition of SIIS, the following test is proposed. Rattlesnakes should be observed in two predatory situations. In one, the subject is presented with a mouse which it is permitted to strike and ingest before the introduction of a second mouse. In the second, the subject is given the opportunity to strike a mouse but then the mouse is immediately removed. This snake should then be "yoked" to the first subject with respect to the time it takes to ingest the mouse, before the second mouse is introduced. The dependent variable in both conditions would be the latency to strike the second mouse. A preliminary version of this study was conducted with 2 rattlesnakes (C. durissus culminatus) of similar age and size. The subject allowed to ingest the first mouse displayed the shortest latency in striking the second mouse (35 seconds vs. 162 seconds), suggesting that consummation of the predatory sequence by swallowing can actively disinhibit SIIS.

If sufficient time (about 20 minutes) passes after an initial strike, the SIIS effect will eventually dissipate and a second prey will be struck with a short latency, even though the first prey was removed before it could be swallowed (Chiszar, et al., Exp. 2). However, on the basis of Figure 2b and the data just reported, it appears that stimulation arising from the act of swallowing can result in more immediate disinhibition.

It appears that striking occupies a pivotal role in rattlesnake predation by releasing chemosensory searching and simultaneously inhibiting the release of further strikes. The dual effects of striking allow us to understand how components of the overall predatory pattern occur in a clear and regular sequence. The modal pattern consists of: (A) prey detection, (B) striking, (C) chemosensory searching, (D) location of the dead prey item, (E) location of the prey's head, and (F) swallowing of the prey head first. The reason that components B, C, and D rarely occur out of order is that B is a prerequisite for C; the occurrence of B and/or C then inhibits a reoccurrence of B and, thereby, increases the probability that D will occur. Once D occurs, E and F are likely to be facilitated since the snake will now be in the immediate presence of tactile cues associated with the dead prey.

Reptile curators from several zoos have reported (personal communication to CWR) that venomous snakes which have refused to feed can often be induced to do so if they can be forced to strike a mouse. This may be done by "teasing" the snake with a mouse until the snake strikes defensively. The predator then behaves as if the strike was based on predatory motivation: chemosensory trailing and ingestion occur more-or-less normally. This observation is understandable in light of our suggestion that the feeding sequence is a series of events with each increasing the probability that the next will occur. When a snake is forced to strike a mouse defensively, the keeper has broken into the series of events and the snake merely completes the sequence.(3)

FOOTNOTES

(1) The ophidian vomeronasal system consists of paired sensory organs (Jacobson's organs) located in the roof of the mouth. The bifid tongue brings molecules into the mouth and deposits them on the roof

from which they are drawn, probably by ciliary action, into the Jacobson's organs. Accordingly, tongue-flick rate can be used as an indication of vomeronasal sensory activity. Neural signals arising in these organs are conducted by the accessory olfactory nerves to the forebrain (nucleus sphericus; Halpern, 1976).

(2) It is important to keep in mind that our snakes were housed individually. Group housing can result in quite different behavior as snakes compete for prey items. We suspect that individual housing best approximates the natural predatory situation in rattlesnakes. Also, SIIS may be more effectively induced by a single strike in adult rattlesnakes than in young ones. Finally, there may be a negative correlation between "nervousness" and the extent to which SIIS is observed in particular individuals or taxa.

Reproduction of the Gray-Banded Kingsnake, Lampropeltis mexicana alterna

Reproductive data of the Gray-banded Kingsnake, Lampropeltis mexicana alterna are scant in literature. Gehlbach & McCoy (1965) noted five large eggs ready for oviposition in a specimen found on 16 May 1964. They averaged 12 mm x 30 mm. Tanzer (1970) reported on a clutch of six eggs laid by an alterna color phase collected on 26 June 1969. The eggs averaged 18.3 mm x 35.1 mm. The young averaged 255.4 mm total length and exhibited both alterna- and blairi color phases. Turner (1977) reported on two alterna hatching from a single egg. No further information on reproduction in this species appears to be available. This report deals with captive breeding, time the female carried the eggs, oviposition and incubation period of the eggs. The measurements of the young are also included.

The female L. m. alterna was received in July 1974, at which time the snake's length was 450 mm; her length at the time of writing was 915 mm. The 895 mm male has been in captivity since May 1975. The snakes are housed separately in 10 gallon Meta-frame slide-top reptile tanks. Newspaper is used for cage lining; room temperature varied from 24°C to 28°C prior to the snakes being placed together. Both snakes fed and were active all winter. The female was placed in the male's cage each night at 2000 hours on 1, 2 and 3 April 1976 and removed each morning. The male actively pursued the female around the cage; attempts to copulate were observed, but no actual copulation was seen.

The female shed on 8 May 1976 and refused food after this date. Her weight was recorded on 12 May 1976 at 227.1 grams. On 15 May 1976, the female was placed in a 5 1/2 gallon aquarium half filled with a mixture of three parts potting soil and one part water. The snake burrowed under the surface of the soil, forming a cavity which could be observed through the glass side of the cage.

At 17:10 hours on 17 May 1976, the female was observed coiled around a clutch of eight eggs. Seven eggs were adherent and white with a smooth texture. The egg which was not adherent was discolored and later proved to be infertile. An attempt to remove the eggs at this point resulted in a display of aggressive behavior by the female which included hissing and attempts to bite. At 19:30 hours, the snake had left the eggs and was crawling about the cage. At this point, all aggressiveness had disppeared and she was removed, weighed, and placed

in her normal cage; she immediately accepted a dead mouse. The female's weight was 139.6 grams.

The eight eggs were measured with a vernier caliper and weighed on a triple-beam balance. Egg diameter was 20 mm for each one; egg length varied from 37 mm to 43 mm (mean 39.8 mm) and clutch weight was 83.7 grams (Table 1).

The eggs were placed in a medium of vermiculite and water (Tryon, 1975) in a plastic box, which was kept on a desk near a window where it received daylight exposure; temperature within the box varied from 28°C to 32°C.

On 23 July 1976 after 66 days, the non-adherent egg collapsed; when opened, it proved infertile. On 25 July 1976, slits appeared in the remaining eggs. By 28 July 1976, all the hatchlings had emerged from their eggs.

The young were weighed on a triple-beam balance and measured by use of a string and plastic rule calibrated in mm. The weight of the young varied from 7.6 grams to 9.5 grams (mean = 8.6) and the length of the young varied from 250 mm to 270 mm (mean = 257.1 mm (Table II)). Ecdysis first occurred on 5 August 1976. All accepted pieces of lizard (Sceloporus, Uta and Eumeces; Sceloporus was preferred) or dead pink mice rubbed with a lizard. Shortly after their first meal, the hatchlings were induced to accept newborn mice either live or dead.

SPINY CHUCKWALLAS BRED AT THE FORT WORTH ZOO

The spiny chuckwalla (Sauromalus hispidus) inhabits Isla Angel de la Guarda and adjacent islands in the Gulf of California. On July 29, 1977, one of (our) specimens laid 21 eggs. Twenty of the eggs were incubated in a five-gallon aquarium on a substrate of vermiculite. Temperature was maintained at 32°C. Five eggs (three of which were fertile) were discarded within a few days due to infection. After 94-99 days incubation, 15 chuckwallas hatched.

This is believed to be a first captive hatching. Since little is known about the young or behavior of S. hispidus, we are looking forward to studying growth and ontogeny of behavior in this species. (G. Carl)

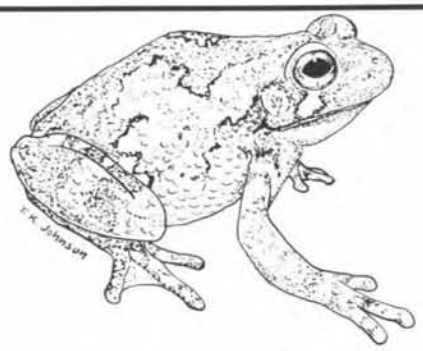
Some Aspects of Breeding and Raising Aquatic Chelonians: Part II

REPRODUCTION, EGG-LAYING AND HATCHING

Care must be taken to observe any type of courtship or copulatory behavior so that preparations can be made for egg-laying. Most aquatic turtles perform certain ritualized courtship activities (Barton and Price, 1955; Ernst and Barbour, 1972; Lardie, 1975, and many others). This may vary among taxa but is always initiated by a heightened general interest in females by the males. At most times of the year, members of the opposite sex are generally ignored. Captive conditions may or may not stimulate reproductive periodicity that corresponds to behavior in nature, so frequent observation is essential. Initial interest may result in one or more males following a female as she swims. Courtship patterns may be instigated by a male caressing the female with long claws of the forelimbs, as in certain Chrysemys and Pseudemys (Ernst, 1971), or by the male closely examining the head and vent of the female, as in Graptemys versa (personal observation), and Graptemys pseudogeographica (Ernst, 1974). Usually, if the female does not attempt escape or appears submissive to advances, copulation occurs. Some species, such as Clemmys muhlenbergi, may copulate regardless of the female's escape behavior (Tryon and Hulsey, 1977). A general copulation pattern for aquatic turtles has been described by Porter (1972). It should be noted that the male will occasionally nip at the female's neck during courtship and mounting. This can be severe, and it can be assumed that females with raw or cut dorsal neck skin have at least been pursued by a male. Copulatory durations observed at the zoo are short, lasting but several minutes for most species; however, several coital sequences may be observed in a single pair during a period of a few hours.

If a suitable nesting area is not provided, the female may retain the eggs which could be ruined once laid. Within several weeks after copulation, females will spend more and more time on land, most often in some secluded shelter or buried beneath material provided for oviposition. Sphagnum moss is perhaps the most suitable nesting material, and there should be enough to allow the females to burrow completely. Most often, a pan of appropriate size is filled with damp sphagnum and placed in the exhibit during the laying season, or kept year-around in off-exhibit enclosures as mentioned in Part II. Females of various species are often seen resting in or under the sphagnum and usually display little or no territorial behavior. If considerable territorial behavior is observed, more than one nesting area must be provided. Digging with alternating hind limbs is a good sign of imminent egg deposition (Punzo, 1975), as is continued burrowing beneath the nesting material. At this time, nests should be checked several times per day. Usually, those females that carefully lay their eggs in a nesting area produce fertile clutches. Conversely, eggs scattered about the enclosure, laid days apart, or laid in the water despite available nesting areas are almost assuredly inviable. Inviability, however, may be due solely to submersion in water (see Ragotskie, 1959; Plummer, 1976).

Once eggs are discovered, it is essential that they be removed from the nesting areas and incubated artificially. All eggs should be measured for length and width with calipers and for weight on a triple-beam balance. It is imperative that the eggs remain in the same position as laid. Careless handling can result in a suffocated embryo due to alteration of the air space within each egg. Immediately after measurements are recorded, eggs should be placed in a one-to-one ratio of ounces of vermiculite (expanded gypsum) to fluid ounces of water in well-sealed glass gallon jars or glass aquaria (Tryon, 1975). Ratios of six oz. to six oz. for one gallon jars and 20 oz. to 20 oz. for ten gallon aquaria seem ideal. I have used setups with a higher percentage of water with success, but an equal or slightly lower percentage of water is preferred. The eggs are spaced apart with their longitudinal axes parallel to the vermiculite surface. A gallon jar is suitable for two or three large (50-60 mm) eggs; they can be spaced out in rows in an aquarium. Each container should have a well-sealed lid. No additional moisture should be added throughout the duration of incubation. The lids should be removed for one or two minutes every two weeks to replenish the oxygen within the containers and then the containers should be resealed. Egg sites can be numbered on the sides of the jar and tops of the aquaria, but never mark the eggs themselves. Advantages of this method are: 1) eggs are visible and observable, 2) humidity level is established at the beginning of the process, and 3) there is no need to touch the eggs or change incubation materials. Incubation temperatures at the zoo vary seasonally. For eggs laid during the warm months, temperatures may fluctuate between approximately 23°C and 32°C with no apparent harm. During the winter, because of lowered available temperatures, eggs are placed in an incubator which maintains an approximate 30°C temperature. With lowered available temperatures, eggs may take an extended time to hatch (Yntema, 1960, 1964), and with extremely high incubation temperatures, dead or deformed young may result (Cunningham, 1939; Cunningham, et al., 1939; Vinegar, 1974). For most turtle eggs, 28°C to 32°C is preferred. Using this method, close to 100 percent of fertile eggs will hatch. It should be stressed that mishandling of eggs or submersion in water has invariably resulted in death of the embryos.



Pritchard (1967) stated that the incubation period for most species of turtles is two or three months. These periods recorded at the zoo have varied considerably although the incubation technique remained the same for all eggs. The shortest chelonian incubation period was 42 days for Clemmys muhlenbergi, and the longest was 155 days for the crowned hill turtle, Geoemyda trijuga coronata. In my experience, the average is 115 to 120 days, but these were mostly tropical or subtropical forms. It is naturally important for a turtle from a colder climate with shorter summers to have a short incubation period, and this may also hold true for tropical forms from regions exposed to frequent flooding or drought. There is also evidence that some fully developed neonates can overwinter in the egg or nest (Woolverton, 1963; Nemuras, 1967; Ernst, 1976), and as a result new hatchlings may be found in early spring. Another reason for varying incubation periods is the stage of development within the eggs at the time of deposition. Clemmys muhlenbergi embryos may develop to a large degree within the female's body, hence an extremely short incubation period. Also, fertilization within a single clutch of eggs may not occur at one time, and as a result, embryos may be in varying states of development when eggs are laid. This may have been the case with a clutch of three eggs incubated identically from a white-lipped mud turtle, Kinosternon leucostomum, for hatching occurred in 121, 137, and 149 days.

Fungus may develop on eggs for many reasons, but the most common are infertility and an overly moist hatching medium. Usually, infertile eggs will develop fungus within a couple of days to a week after deposition, but it may attack fertile

eggs during any stage of development after continuous exposure to excessive moisture. If this occurs, the eggs can be carefully taken out of the containers, wiped off with a damp cloth, and replaced in a dryer medium. If growth persists, application of a broad spectrum antibiotic salve such as Biotef (Upjohn Co.) or Forte-topical (Upjohn Co.) has been moderately successful in preventing further growth.

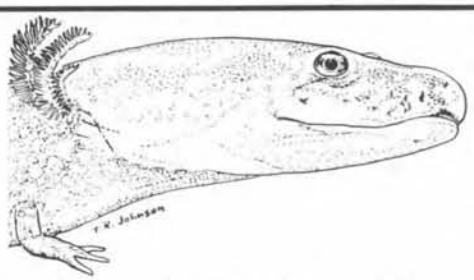
Reptile eggs, like poultry eggs, may be candled in order to determine fertility, although other methods exist (Quay, 1976). Several commercial poultry scanners are available; however, one can be easily made using a tin can and light bulb. Cut a small (1-2 cm) hole in the center of the sealed end of an opened can and place the can over a standard 100 watt light bulb. The eggs can then be backlit by placing them against the hole for a few seconds. If, after the incubation process is well along, there are no signs of solid material within the egg, it is most probably infertile. Those eggs which appear solidly dark and allow no passage of light probably contain developing embryos. The success of this method depends a great deal upon the point at which the eggs are candled. For example, at the Fort Worth Zoo, an entire clutch from Alligator mississippiensis was candled after 30 days of incubation, which is approximately one third of the total incubation time. It was thought that fertility could be determined at this point. Although none of the eggs showed obvious signs of fertility, almost all hatched after 90 to 100 days.

Hatchling turtles, like other egg-laying reptiles, possess an egg-tooth on the proximal edge of the snout with which they cut the shell prior to emergence. The head is moved vertically, horizontally, or rotated in a circular fashion with the sharp edge of the egg-tooth pressed against the inner shell lining. In most species with oval eggs, the young turtle will cut one end of the egg as it cannot turn around within the egg. In most circular eggs, such as those of Chelonia, Chelydra, or some tortoises, the slits may be more varied in location. Once the egg is opened the hatchling may rest for a period of several hours to several days before attempting further progress (Einem, 1956). It is a mistake to manually open the egg and extract the young turtle at this point. Usually, during the first stages of hatching there is some remaining yolk attached to the plastron. This may take several days to be absorbed, during which time the plastron will slowly close up and assume normal proportions. Chances of infection and stress are increased if the hatchlings are extracted before this occurs.

JUVENILE MAINTENANCE

Conditions of maintenance for newly hatched and juvenile turtles are necessarily more exacting than those for adults. Improper care during the first several months after hatching will usually mean the difference between a healthy, reproductively active young adult and one that is not. As soon as the young turtles escape the confinement and security of the egg, they should be carefully rinsed off in tepid water and placed in a gallon jar with damp paper towels. Temperature should not be much below or above that of incubation or thermal shock may occur. They should be left in the jar for 24 to 48 hours, depending upon the amount of unused yolk remaining. Measurements should be taken 24 hours after emergence for carapace length and weight using procedures described earlier for eggs. Because it is important to check development in appearance as well as growth, photographs should be taken at this time. Many chelonians begin to lose juvenile characteristics of color and shell contour after several weeks of feeding (Adler, 1960).

If yolk retention has been minimal, the turtles should be placed in a 19 liter aquarium, tilted so that dry and wet areas are provided, with approximately 2.5 cm water at the deepest point. Scattered sphagnum moss and small pieces of cork bark may be added for hiding. Certain species, such as Clemmys muhlenbergi, will spend most of the first couple of weeks hidden from view beneath the sphagnum in the water. Others, such as Geoemyda trijuga, are unintimidated and active. It is best to provide some areas for hiding for hatchlings of all species.If feeding and growth appear to be progressing normally after one or two months, the juveniles should be moved to a 38 liter aquarium where they will spend much of their first year. Small pea gravel is used as a substrate and should be sloped at one end for depth variation. Maximum water depth should vary from 5.0 cm to 7.5 cm depending on turtle size. Cork bark and rocks should be arranged for basking and hiding.



Each aquarium should be supplied with an airstone or power type filter. These filters can be lowered outside the tanks so that they will function with a low water level. Because such filters are capable of keeping the entire 38 liter tank relatively clean when full, maximum cleanliness can be attained with the reduced level. Each enclosure should be thoroughly cleaned once each week to ten days using tepid water, and filtering materials should be changed as necessary. Water temperature should be maintained at approximately 25°C, and the temperatures in the dry basking areas should vary seasonally from 25°C to 32°C, although a thermal gradient is preferrable at all times. Murphy (1973) stated that certain species of semi-aquatic turtles require relatively high levels of atmospheric humidity. Boyer (1965) indicated that there is considerable water loss during basking. With a higher humidity, this loss can be kept to a minimum. In addition, growth of some juvenile turtles increased significantly when humidity was raised to 95 to 100 percent in their enclosures (Zovickian, 1971). This can be accomplished by covering the aquaria with pieces of glass or clear plastic, but the use of these materials can eliminate essential ultra-violet radiation. Also, air circulation is severely reduced. At the zoo, increased humidity and provisions for lighting are accomplished simultaneously through the use of single 20 watt (two foot) Vita-lite (Durotest Co.) fluorescent tubes in reflectors that rest directly on and over the open tank tops and filtering tubes. These reflectors help to retain heat which increases the rate of evaporation, and because they cover approximately 75 percent of the open tops, humidity is raised considerably during the lighting cycle (0800-1730 h). Vita-lite tubes appear to supply the necessary ultra-violet radiation for hatchling and juvenile turtles and at the same time restrict the growth of harmful bacteria. As in the larger exhibits, daylight hours are generally extended through the use of clear skylights.

It is extremely important that a strict routine of feeding be established as soon as possible after hatching. Most species will begin to show feeding responses 24 hours after hatching. For approxiately the first six months after hatching, juveniles should be placed individually in small plastic bowls with just enough tepid water to cover the top of their carapaces. Bowl feeding is recommended for all species for several reasons. 1) Feeding outside the enclosure provides a degree of cleanliness otherwise impossible without almost daily water changes, and because of stress and high chlorine content (Murphy, 1973) this should be avoided. In addition, chances of disease are increased

when food items are introduced into the living area. 2) The amount of food consumed by each turtle can be closely checked. Appetite patterns can be established for each, and the amount of food can be decreased if obesity occurs or increased if growth does not seem satisfatory. 3) Many juveniles may refuse to feed because of intimidation by stronger and more aggressive tank-mates. Without competition, even the shyest individual will most probably consume a sufficient amount at each feeding. 4) Feeding usually stimulates defecation which is accomplished in the feeding bowls and not in the enclosure. 5) Even several non-aggressive juveniles in one feeding area can be a danger by biting or drowning one another. When it has been determined that several individuals will feed well together, they may be placed communally in larger containers.

Begin feeding most hatchling turtles on a three day per week schedule for the first month. At this time, they should be weighed and measured to compare with hatching size. If little or no growth is recorded, then feeding should be increased to five days in a row. Thereafter, measurements should be taken at monthly intervals. For example, three hatchling Geoemyda trijuga thermalis had mean measurements of 39.3 mm carapace length and a mean weight of 11.1 g. These turtles were maintained on a three day per week routine and grew to a mean carapace length of 80.0 mm with a mean weight of 80.0 g in one year. Growth was rapid, but each turtle maintained a normal appearance. On the other hand, two Clemmys muhlenbergi maintained from hatching to one year of age increased in carapace length and body weight from a mean of 24 mm/3.3 g, to 57mm/35.0 g on the five day per week diet (Tryon and Hulsey, 1977). Conversely, two other C. muhlenbergi were maintained on a three days per week schedule and increased from a mean 25.0 mm/3.5 g at hatching to a mean 31.7 mm/5.9 g after six months, at which time they were established on a five day schedule. Growth in length and weight increased considerably after the start of the seventh month. Ideally, growth should progress uniformly and increases of 3 to 5 mm with an equal weight increase in grams should be expected each month during the first year for many species reaching 100 mm to 200 mm adult carapace length. After the first year, growth may slow down considerably and become irregular.

Though there may be a dietary shift of food preferences in turtles from hatching to maturity (Clark and Gibbons, 1969), variety is the key to successful juvenile feeding. Turtles receive a different food item with each feeding and are normally fed until they appear full. Some species will consume their meals completely, others will feed and then remain inactive for some time before resumption. For this reason it is best to leave the turtle in the feeding bowl at least two hours with available food items. A typical five day schedule is as follows: Day 1 -- chopped mouse entrails; Day 2 -- small live crickets; Day 3 -- chopped fresh minnows; Day 4 -- live earthworms, chopped or whole, depending on turtle size; Day 5 -- turtle gelatin, as described in Part I. Occasionally, small fragments of the multiple vitamin Unipet (Upjohn Co.), which most species will eat unmixed and undissolved, should be added. Once feeding is completed, each turtle should be rinsed off in tepid water and placed back in its enclosure, where it will continue to forage. Foraging is constant preoccupation with juveniles in nature.

Once the juveniles reach 50 to 80 mm carapace length, they should be transferred to a larger aquarium, on or off exhibit. It is preferable to move them to a wooden box such as described in Part I for off-exhibit housing. These may vary in size, but all should provide the same conditions of temperature, lighting, basking and hiding areas. Additional space will allow for much more exercise, and this will usually stimulate an increase in growth. Also at this time, the juveniles may begin their seasonal indoor-outdoor cycles, and are well on their way to maturity.

CONCLUSION

Certainly, many other successful techniques for breeding and raising aquatic chelonians are in use, and some may be less time consuming and produce better results. This report cannot possibly cover all aspects of captive maintenance, nor does it pretend to be all-encompassing. With the simplistic set-ups of housing, lighting and feeding techniques described, it does, however, present a common sense approach for attaining the desired results. These techniques are presently in use at the Fort Worth Zoological Park, but are being improved continuously. Zoo personnel and individuals involved in the maintenance of captive chelonians have their own ideas and techniques that are being constantly shared. Perhaps eventually an ideal can be achieved.

Geographic Distribution

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same. The standard format for a geographic distribution record is:

Scientific name (common name) as it appears in Conant (1975) or Stebbins (1966). Locality (use metric for distances). Date and collector(s). Identified or verified by. Place of deposition and catalogue number. Comments. Citation. Submitted by (give name and address).

Please submit new geographic distribution records in the standard format only to Joseph C. Mitchell, Graduate Program in Ecology, University of Tennessee, Knoxville, Tennessee 37916. Short manuscripts are acceptable when data cannot be adequately presented in the standard format.

Recommended citation for new geographic distribution records appearing in Herpetological Review is: Jones, J. 1977. Geographic distribution: Rana pipiens. SSAR Herp. Review 8(1): 1.

CAUDATA

AMBYSTOMA LATERALE (Blue-Spotted Salamander). USA. CONNECTICUT: Hartford Co.: Bloomfield, 0500 meters N of Adams Road along Griffin Brook. 30 September 1973. R. Jones. Verified by B.W. Menzel. Univ. Connecticut Mus. Nat. Hist. nos. 6643-6645. Confirms presence of this species in Connecticut (Uzzell, 1967. Cat. Amer. Amph. Rept. 48.1)

Submitted by MICHAEL W. KLEMENS and ROBERT E. DUBOS, University of Connecticut Museum of Natural History, Department of Systematic and Evolutionary Biology, Biological Sciences Group, University of Connecticut, Storrs, Connecticut 06268.

ANURA

BUFO AMERICANUS CHARLESMITHI (Dwarf American Toad). USA. LOUISIANA: DeSoto Parish: Mansfield. May 1972. T.L. Hibbitts. Verified by W. Seifert. Dallas Mus. Nat. Hist, DMNH 4348. Extends known range into northwestern Louisiana (Conant, 1975 A Field Guide to Reptiles and Amphibians, Houghton Mifflin Co.). TEXAS: Red River Co.: 22.5 km NE Clarksville, Picina Farm. 15 May 1971. W. Seifert. Verified by W. Seifert. Dallas Mus. Nat. Hist., DMNH 804. Cranial crests more closely resemble Bufo valliceps having two preparotoids and relatively long parietal spurs, suggesting some intergradation with B. valliceps. (Raun & Gehlbach, 1972, Amphibians and Reptiles in Texas, Dallas Mus. Nat Hist. Bull. No. 2).

Submitted by WAYNE SEIFERT, Dallas Museum of Natural History, P. O. Box 26193, Dallas, Texas 75226.

HYLACTOPHRYNE AUGUSTI LATRANS (Barking Frog). USA. TEXAS: Ward Co.: Pyote Air Force Base, Pyote. 1 May 1976. Collected by two members of the Texas Herpetological Society. Verified by W. Seifert. Dallas Mus. Nat. Hist., DMNH 4647. Collected in a sump pump hole in the machine room of the abandoned base. The surrounding area is flat and has red sandy soil with mesquite (Prosopis glandulosa) and creosotebush (Larrea divaricata) being the dominant vegetation. Numerous gopher (Geomys) burrows may be the only natural habitat for these frogs. This specimen is a link between the New Mexico and Texas specimens and its locality falls on the question mark of Conant's (1975. A Field Guide to Reptiles and Amphibians of Eastern and Central North America) range map.

Submitted by WAYNE SEIFERT, Dallas Museum of Natural History, P. O. Box 26193, Dallas, Texas 75226.

HYPOPACHUS VARIOLOSUS (Sheep Frog). MEXICO. AGUASCALIENTES: 13.5 km (by mex. 70) ENE Calvillo. 8 July 1977. D. Frost and S. Aird. Louisiana St. Univ. Mus. Zool., LSUMZ 36075-76. First record for the state of Aguascalientes and the most northern record in the Rio Juchipila drainage (Nelson, 1974, Herpetologica 30: 250-274). Associated species were Bufo occidentalis, Hyla eximia, Rana montezumae and Scaphiopus multiplicatus.

Submitted by DARREL FROST, Museum of Zoology, Louisiana State University, Baton Rouge, Louisiana 70893, and STEVEN AIRD, Department of Biochemistry, Louisiana State University Medical School, New Orleans, Louisiana 70112.

TESTUDINES

DERMOCHELYS CORIACEA (Leatherback Sea Turtle). USA. CALIFORNIA: Ventura Co: Ventura. 2 September 1977. Skull deposited in Santa Barbara Museum of Natural History, SBMNH 1361. Carapace length 124 cm. First record for the county and supplements previous records in southern California (Van Denburgh, 1922, Occ. Pap. Calif. Acad. Sci., 10 (1-2): 1-611, 617-1028; Slevin, 1927, Copeia (159): 172-173; Lowe and Norris, 1955, Copeia (3): 256).

Submitted by FRED LOTTER, Biology Department, Ventura College, Ventura, California 93003.

SAURIA

EUMECES ANTHRACINUS PLUVIALIS (Southern Coal Skink) USA. TEXAS: Dallas Co: Oak Cliff, Dallas Zoo. 17 July 1975. D. Barker. Verified by J.R. Dixon and W. Seifert. Texas A&M University and Dallas Mus. Nat. Hist, DMNH 2268. Range extension of three counties east (Raun and Gehlbach, 1972, Amphibians and Reptiles in Texas, Dallas Mus. Nat. Hist. Bull. No. 2).

Submitted by WAYNE SEIFERT, Dallas Museum of Natural History, P. O. Box 26193, Dallas, Texas 75226.

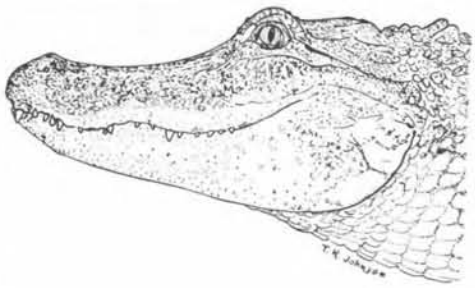
GERRHONOTUS LIOCEPHALUS INFERNALIS (Texas Alligator Lizard).USA. TEXAS: Dallas Co: Clarendon Dr. and Cumberland St., Dallas. 11 November 1973. J.B. Murphy. Verified by W. Seifert. Dallas Mus. Nat. Hist., DMNH 2210. The habitat is "typical" and could harbor an isolated population surrounded by the city although

no additional specimens have been collected (Raun and Gehlbach, 1972, Amphibians and Reptiles in Texas, Dallas Mus. Nat. Hist. Bull. No. 2).

Submitted by WAYNE SEIFERT, Dallas Museum of Natural History, P. O. Box 26193, Dallas, Texas 75226. ●

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA. FLORIDA: St. Lucie Co: Ft. Pierce. 21 September 1977. S. Myers and S. Phillips. Verified by W. Auffenberg, Florida State Mus., FLS/UF 40645-40649. 12 February 1974. J. Fallon, Florida Med. Entom.Lab Collection, uncatalogued. E.W. Campbell, no date, FSM/UF 40650. This locality lies 368.5 km south of the Jacksonville record (Meylan, Herp. Rev. 8(2): 39) and 202.7 km north of the Miami record (Barbour, 1936, Copeia 1936 (2). Ft. Pierce is a port of entry and this is undoubtedly how the population was introduced.

Submitted by STEVEN MYERS, Indian River Community College, Mueller Center, Lundberg Road, Vero Beach, Florida 32960. Mailing address: 705 Wall Street, Vero Beach, Florida 32960. ●



SERPENTES

CARPHOPHIS AMOENIS VERMIS (Western Worm Snake). USA. WISCONSIN: Grant Co: Nelson Dewey State Park, T3N, R6W, Sec 13, SW 1/4 of NE 1/4. 14 May 1977, 18 June 1977. R.A. Sajdak. Milwaukee Pub. Mus. Herpetol. Collection, MPM #14754, 15181. First record from Wisconsin. Nearest published localities are 235.3 km. S near Keosauqua, Iowa (Bailey, 1939, Copeia, 4: 218-219) and ca.255 km S in western Illinois (Smith, 1961. Illinois Nat. Hist. Surv. Bull. 28(1): 1-298).

Submitted by RICHARD A. SAJDAK, Zoology Department, University of Wisconsin-Milwaukee, Milwaukee, Wisconsin 53201. ●

MICRURUS LATICOLLARIS (Mexican Coral Snake). MEXICO. OAXACA: 4.3 km (by Mex. 125) NE Cuyotepeji. 16 June 1977. D. Frost and S. Aird. Louisiana St. Univ. Mus. Zool., LSUMZ 36213. First record for Oaxaca and the most eastern locality for this species. Our specimen extends the known range ca. 115 km SE of the nearest published locality, "probably Matamoros, Puebla" (Schmidt, 1958, Fieldiana Zool. 39: 201-212).

Submitted by DARREL FROST, Museum of Zoology, Louisiana State University, Baton Rouge, Louisiana 70893, and STEVEN AIRD, Department of Biochemistry, Louisiana State University Medical School, New Orleans, Louisiana 70112. ●

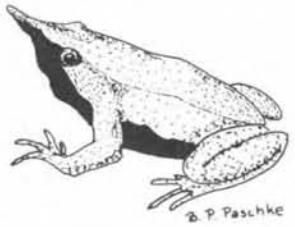
Rhinocheilus lecontei tessellatus (Texas Long-nosed Snake). MEXICO. ZACATECAS: 2.7 km (by Mex. 70) SW Aguascalientes state line. 9 July 1977. D. Frost and S. Aird. Louisiana St. Univ. Mus. Zool., LSUMZ 36252. First record for southern Zacatecas, southernmost locality for the subspecies and a range extension ca. 175 km WSW of the nearest known locality, in San Luis Potosi (Medica, 1975, Cat. Amer. Amph. Rept.: 175.1-175.4) R.l. tessellatus is as yet unreported in either Aguascalientes or Jalisco but the proximity of this Zacatecas locality to both state lines insures the presence of this subspecies in those states.

Submitted by DARREL FROST, Museum of Zoology, Louisiana State University, Baton Rouge, Louisiana 70893, and STEVEN AIRD, Department of Biochemistry, Louisiana State University Medical School, New Orleans, Louisiana 70112. ●

SALVADORA GRAHAMIAE LINEATA (Texas Patch-nosed Snake). USA. TEXAS: Robertson Co: 4.8 km S Franklin. 8 February 1970. T.L. Hibbitts. Verified by W. Seifert. Dallas Mus. Nat. Hist., DMNH 4312. Extends known range one county eastward and represents the most eastern locality for Salvadora (Raun and Gehlbach, 1972, Amphibians and Reptiles in Texas, Dallas Mus. Nat. Hist. Bull. No. 2).

Submitted by WAYNE SEIFERT, Dallas Museum of Natural History, P. O. Box 26193, Dallas, Texas 75226. ●

SYMPHIMUS LEUCOSTOMUS (Mexican White-Lipped Snake). MEXICO. OAXACA: 11.2 km N La Ventosa. 21 December 1976. J.L. Knight and J.D. Johnson. Herpetology collection, Lab. for Env. Bio., Univ. Texas at El Paso. (UTEP; number to be assigned). Fills the geographic hiatus of ca. 130 km between the vicinity of Tehuantepec, Oaxaca and 15 km N Arriaga, Chiapas (Rossman and Schaefer, 1974, Occ. Pap. Mus. Zool.45: 1-12).



Submitted by JERRY D. JOHNSON, Department of Biology, El Paso Community College, El Paso, Texas 79904 and JAMES L. KNIGHT, Department of Biology, Emporia State University, Emporia, Kansas 66801. ●

SYMPHOLIS LIPPIENS MEXICO. JALISCO: 7.1 km SW Guadalajara bypass on Mex. 15 to Morelia (=ca. 10 km SW Guadalajara), San Jose de Tajo trailer park. Ca. 20 June 1977. Collected by a local resident. Verified by D. Frost. Louisiana St. Univ. Mus. Zool., LSUMZ 36217. The collector reported this species to be uncommon but seen occasionally after hard rains have forced them to the surface. First record for the vicinity of the type locality (Guadalajara) and the state of Jalisco since the species was described by Cope (Proc. Acad. Nat. Sci. Philadelphia 13: 524) in 1862 ("1861"). This specimen demonstrates that Sympholis lippiens penetrates into oak woodland and probably follows the more tropical barrancas into eastern Durango and southern Zacatecas.

Submitted by DARREL FROST, Museum of Zoology, Louisiana State University, Baton Rouge, Louisiana 70893. ●

TYPHLOPS COSTARICENSIS (Costa Rican Blind Snake). NICARAGUA: Departamento de Metagalpa: San Jose de la Montana, near Ciudad Metagalpa, 1100 m. Dug out by bulldozer August 2, 1975, and collected by J. Villa. Verified by S. B. McDowell. Amer. Mus. Nat. Hist., #113546. The specimen is a female with empty but well developed right oviduct (left one absent); total length 262 mm (tail: 3.3). The locality represents the first documented record for Nicaragua and a range extension of ca. 280 km NNW from the type locality. The species was hitherto known from Monteverde, Costa Rica (Jimenez and Savage, 1962: Rev. Biol. Trop. 10: 199-203) and based on a single specimen; others are now available, making a total of 7: NICARAGUA: Matagalpa, no other data (Mus. Comp. Zool., Harvard, #9558, a badly mutilated specimen mis-identified as T. tenuis); COSTA RICA: Puntarenas Province; Monteverde, Sierra de Tilaran, 1500 m (Mus. Zool. Univ. Costa Rica #2215, 4362, 5229, and R.K. LaVal #3084). T. costaricensis was included in the Nicaraguan herpetofauna (Villa, 1971: Lista Tentativa de Vertebrados Inferiores de Nicaragua) on the basis of the MCZ specimen, but documentation was pending.

Submitted by JAIME VILLA, Department of Biology, University of Missouri, Kansas City, Missouri 64110. ●

Two Snakes, Leptophis modestus and Pelamis platurus, New to the Herpetofauna of Honduras

Recent work has demonstrated the presence of two additions to the list of snakes known from Honduras, as prepared by Wilson and Meyer (in press). These additions are described below.

LEPTOPHIS MODESTUS (GUNTHER)

On the evening of 31 May 1976, we collected a DOR specimen of Leptophis modestus (Gunther) at 1890 m approximately 22.5 km E Nueva Ocotepeque, depto. Ocotepeque in the Sierra de Merendon of extreme southwestern Honduras. The specimen (LSUMZ 33571) represents the first Honduran record of this species, recently resurrected by Hoyt (1964).

The Honduran specimen is a female with the following characteristics: ventrals, 180; anal plate divided; subcaudals, 168 (count approximate as tail is badly damaged); dorsal scale reduction formula 15-7(114) 133+4(115)11; supralabials 8-8, with 4th and 5th entering orbit; infralabials 10-10; loreal 1-1; preocular 1-1; postoculars 2-?; total length, 752 mm; tail length, 274; ratio of tail to total length, 0.364. All dorsal body scales are keeled, except for the outermost row, the degree of keeling decreasing gradually laterally. The color in life was green dorsally and pale green ventrally. The black postocular bar begins on the lower postocular and passes posteriorly along the lower portion of the anterior temporal and the upper edge of supralabials 6 and 7 onto the lower portion of the lower posterior temporal and upper portion of supralabial 8. The above description agrees well with that given for Guatemalan and Salvadoran specimens by Hoyt (1964) and the Mexican specimen by Williams and Smith (1966).

The Honduran specimen came from just below the point where the Carretara Occidente crests the Sierra de Merendon. The vegetation in this area originally was cloud forest (Lower Montane Moist Forest formation of Holdridge, 1964). Some patches of apparently undisturbed cloud forest exist there now but much has been destroyed and is covered with second-growth forest, pasture, and crop fields.

Leptophis modestus is now known to occur at moderate and intermediate elevations of both versants (not only the Atlantic versant, as stated by Williams and Smith, 1966; Cerro Monte Cristo, the mountain from whence came the Salvadoran specimens, lies on the Pacific versant, the Guatemalan locality is on the Atlantic versant, and the Honduran locality essentially straddles the Continental Divide) in three separate areas, as currently understood, in northeastern Chiapas, central Guatemala, and extreme northwestern El Salvador-southwestern Honduras. The data on elevation supplied for specimens discussed by Hoyt (1964) and Williams and Smith (1966) indicate a known range of 1335-2200 m. For reasons unclear to us, Williams and Smith (1966) gave a range of 1250-2250 m. The vegetational limits for the species are difficult to determine at present. No elevational or vegetational data are available for the Guatemalan specimen, although it apparently came from the Rabinal-Cubulco Basin feeding out of the middle portion of the Sierra de Chuacus, which was described by Stuart (1954) as being covered by a pine savanna with "short grasses and dry-land shrubs" in the more easterly portions. Williams and Smith (1966) implied that the Chiapan specimen came from a pine-oak forest, a type of vegetation common to the intermediate elevations (between 1000 and 1500-2000 meters, depending upon exposure) of the Central Highlands of Guatemala and Chiapas. Hoyt (1964) gave no indication of the type of vegetation from which the Salvadoran specimens came, but Uzzell and Starret (1958) described the area as covered by "virgin cloud forest," except where cleared for pasture. Essentially the same situation is to be found at the Honduran locality. The vegetation of the area has been characterized by Meyer and Wilson (1971) as Lower Montane Moist Forest (or, vernacularly, "cloud forest") and is illustrated by Meyer (1969, fig. 24). In summary, as best as can be presently determined, Leptophis modestus occurs in vegetation ranging from pine-oak at lower elevations to cloud forest at higher elevations.

Williams and Smith (1966) stated that Leptophis modestus "appears to be another indicator of the 'subhumid corridor' of Stuart (1954), where it inhabits the oak-pine forest zone." The apparent restriction of Leptophis modestus to humid forest types (Subtropical and Lower Montane Moist Forest formations) effectively exempts it from consideration as a subhumid corridor indicator species, in the sense intended by Stuart (1954).

PELAMIS PLATURUS (LINNAEUS)

During a study of the nesting sites of the Pacific Ridley (Lepidochelys olivacea) in Honduras in 1967, Peter C.H. Pritchard collected three specimens (UF 29075, 29215-16) of Pelamis platurus (Linnaeus) in the Gulf of Fonseca near the coastal town of Cedeno. These specimens represent the first records of the yellow-bellied sea snake in Honduras.

Pelamis platurus is widely distributed in the waters off the Pacific Coast of the Western Hemisphere. It has been previously recorded from all of the countries in Latin America that border the Pacific Ocean between and including Mexico and Ecuador, with the exception of Honduras (Kropach, 1975). The records from the countries of El Salvador and Peru (Hoge and Romano, 1971) appear to be unsupported by specimens from definite localities. Taylor (1951) mentioned its occurrence on Isla de Pascua (Easter Island), a Chilean possession. The occurrence of Pelamis platurus in Honduran marine waters thus was to be expected.

All three specimens are tricolored, but two of them (UF 29075, 29216) show dark spots in the ventral band (sensu Tu, 1976).

The specimens were found washed up on the beach at Cedeno, a small town on the coast of the department of Choluteca.

ACKNOWLEDGMENTS

We are grateful to Peter C.H. Pritchard of the Florida Audubon Society for alerting us to the existence and location of the specimens of Pelamis platurus.

News Notes

Letters to the Editor

26 January 1978

According to an article published in the LA TIMES several weeks ago, several states have considered changing the 'skull-and-crossbones' symbol traditionally used on bottles containing poisonous substances to something which--to children--does not suggest "pirate food".

Several cities have experimented quite successfully with the symbol "Mr. Yuk!" -- the traditional smile button in a distinctly sour mood.

The State of Illinois, however, experimented with young children with other kinds of symbols, and, after suitable expense, showed that one symbol was more effective: a fanged green serpent.

Although I would not like to see youngsters poisoned any more than anyone else, I would also not like to see their minds poisoned by the substitute of phobia for reason. Every herpetologist has had occasion on which he or she has had to deal with the fear of snakes by those who do not know the reptiles, and we all know the difficulty of overcoming that superstititon, far more difficult in the case of snakes than with all other reptiles combined.

From the article, I judge that the state intends to implement the new symbol in the near future.

I believe that this action should be halted.

Were it the only effective way to save children's lives, I might not have misgivings, but I understand that the "Mr. Yuk!" symbol has been 100% effective in areas where it has been tested over a five year period. The green serpent symbol thus further lacks the economic pulse; will pharmaceutical companies produce a separate label for Illinois while so many states switch to "Mr. Yuk!"?

Would we today tolerate the pastiches of German and Japanese character which abounded in the comics produced during WWII? No. Nor do I think we should tolerate any symbiomythico framework which seems to lend credence to superstitions about any of the creatures who share our planet with us.

There are proven ways to discourage children from ingesting poisons which do not encourage them to think ill of an animal of demonstrable economic importance, an animal which herpetologists have defended for nearly a century against ignorance. I do not think we should lend support -- even through omission -- to that ignorance, but feel that this proposal should be actively opposed -- and to hell with the money!

DONALD E. AYRES, 5707 Harold Way #3, Hollywood, California 90028.

COLOMBIAN LIZARD PROJECT

Stephen Ayala is attempting the impossible--putting together a guidebook to Colombian lizards, having collected over 100 of the 150 or so described species.

He is painfully aware of the absence of the required understructure of numerous previous studies, but is trying to put together a set of photographs and descriptions of as many species as possible as a stimulus to further work. If you can help, please write: Stephen Ayala, Ph.D., c/o Tulane University ICMR, A.A. 5390, Universidad Del Valle, Cali, COLOMBIA.

SNAKE MIMICRY INFO NEEDED

Mr. K.R.G. Welch (123 Verbena Way, Worle, Avon BS22 0RW, ENGLAND) is preparing a summary of mimicry (of form, behavior or color in entire species or single specimens) in snakes. He wishes to hear from persons having pertinent data, informal notes or photographs, and would be grateful for any help.

REQUEST FOR INFORMATION

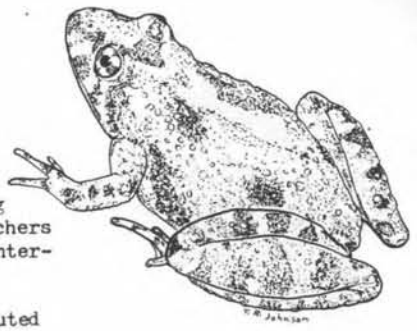
The newly formed Ministerio del Ambiente y de los Recursos Naturales Renovables (MARNR) of Venezuela is commencing a project entitled "Inventario Nacional de Fauna". The inventory will deal with the mammalian, avian, reptilian, and amphibian faunas. It is hoped that, after a year or two of field work, a series of distribution maps can be published in four volumes for the herpetofauna of Venezuela. The proposed volumes will include a bibliography as well as a list of localities covered by the MARNR, and will consist of: Snakes; Lizards and Amphisbaeneans; Crocodylia and Testudines; and Amphibians. At present we are compiling a list of locality records from the literature in order to assess which areas warrant the most attention. Steve Gorzula is in charge of the research into the herpetofauna, and would be grateful to receive information and correspondence. Of particular interest are articles that have been published in regional journals and newsletters, unpublished geographical distribution records, and information about collections of Venezuelan herpetofauna in foreign museums and institutions. Anyone who is able to assist us should write to: Steve Gorzula, MARNR, Div. Fauna, Centro Simon Bolivar, Ed. Camejo, pisol, #124, Caracas 101, VENEZUELA.

DATA ON SPERM STORAGE ABILITIES IN REPTILES DESIRED

For a detailed report on sperm storage abilities in reptiles, all kinds of information, data and observations on this subject are desired from any persons. Main interest is on lizards and snakes. Send replies by air-mail to: Matt E. Braunwalder, Finnsterrutistrasse 5, 8134 Adliswil, SWITZERLAND.

DATA AND INFORMATION NEEDED ON SCOLIOSIS/KYPHOSIS AND KYPHOSCOLIOSIS ON AMPHIBIANS AND REPTILES

Matt E. Braunwalder (address above) is preparing a comprehensive scientific study on scoliosis, kyphosis and kyphoscoliosis as well as other congenital bone deformations. One chapter will be dedicated to amphibians and reptiles. Therefore, he needs specific data, information and documentation on this subject illustrated with photographs or x-rays. Specific interests are: anamnesis; possible causes during gestation of egg clutches and in viviparous species; mortality rate; genetic or other transmittability; attempts and procedures of medical and operative treatments and its specific results; other statistics and data. If literature about this subject is cited, a photostatic copy would be appreciated. All data and information should be airmailed prior to October 31, 1978.



ERRATA FOR HR 9(1)

Page 13, col. 1, para 2, line 15: "nd" should read "and"

Page 15, col. 3, para 2, line 36: after "turtle," add "Geoemyda trijuga thermalis, white-lipped mud turtle,"

Page 15, col. 3, photo caption: add "Photo by John E. Simmons."

Current Literature

As of March, 1978, approximately 87 searchers are scanning 450 journals. Titles are published four times per year. Searchers are encouraged to submit titles for inclusion at three month intervals to assure approximately equal listings in HR.

Anyone publishing in a journal that is not widely distributed is invited to submit a complete citation or send a reprint to insure that the reference is published in Current Literature. Complete citations to obscure references are also welcome.

take five for Safety, Quality and Durability

1 FurMont Reptile Equipment
Flexi-Nets 2
3 Hand Lights
Elephant Hooks 4
5 Protective & Field Equipment

FurMont Reptile Equipment

Fourteen styles of reptile hooks, extendable handles, sexing probes, hiding boxes, Sup-R-Bags, Bag Stiks*.

Flexi-Nets

Modular and custom designed nets. Hoop Stiks, Penta Nets, Net Stik*, Net Stik QC*. Extendable handles. 12 to 30 inch diameters. For felines, primates, small mammals, birds, pinnipeds and fish.

*U.S. Patent No. 3872834

Hand Lights

Ultra-high intensity rechargeable lights for zoo security, field work, expeditions, infrared animal surveillance and egg candling.

Elephant Hooks

Six head styles, three hook styles, four handle styles of fiberglass, aluminum or wood core aluminum.

Protective & Field Equipment

Gloves, gauntlets, aprons, leggings, etc. Custom protective equipment. Custom barrier nets.

Field and expedition tentage, tarps and backpacks by Eureka Tent and Camp Trails.

CATALOG(S) ON REQUEST

Fuhrman Diversified proudly supplies equipment to over 120 zoos and aquariums, 60 universities and 50 other institutions on all 7 continents.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of Herpetological Review in 1967 (Corson Hirschfeld, Editor):

> "Herpetological Review incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the Review will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Now in its tenth year, Herpetological Review remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the Journal of Herpetology -- see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Authors are urged to write the editors before submitting feature-length articles. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles are desired. Submissions should be black-and-white, 8 X 10, glossy prints, and should be accompanied by a descriptive caption and exposure data. The name and address of the contributor should be taped or penciled on the back of each print. Please DO NOT send photographs before corresponding with the editors about them. Return of unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions can be supplied if desired. Contributors will receive ordering information prior to publication of their material. Herpetological Review will accept commercial advertising. Rates and copy information are available from the editors.

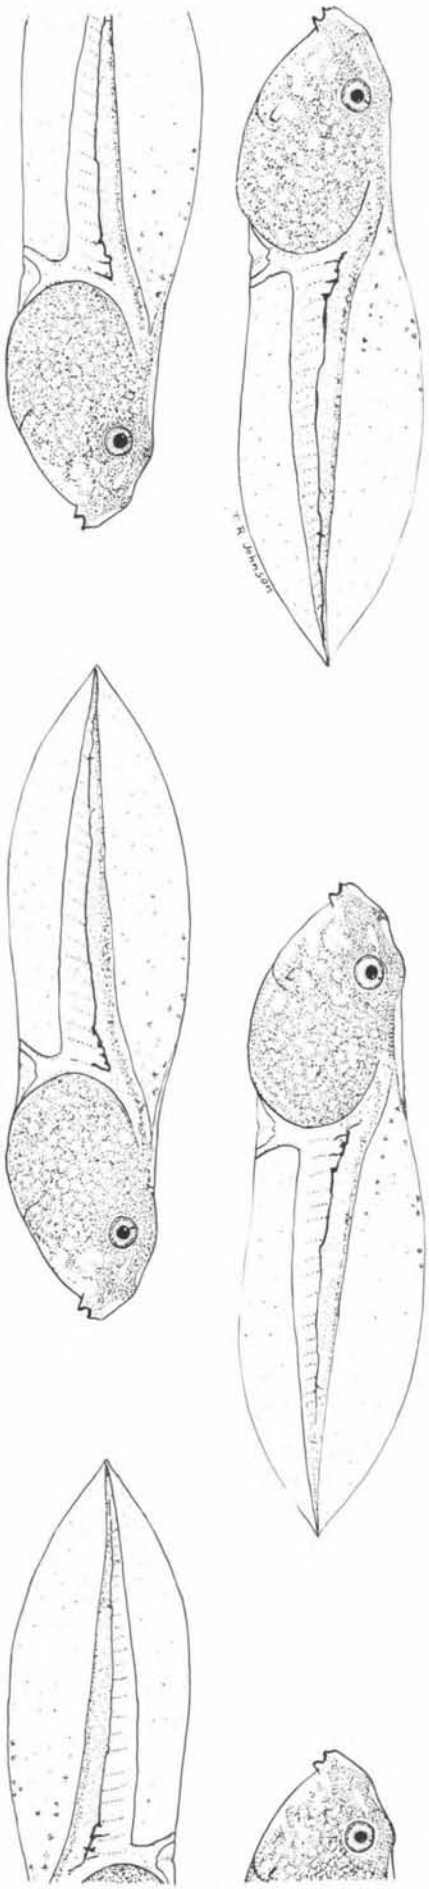
SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the Journal of Herpetology (four issues per year), Herpetological Review (four issues per year), Herpetological Circulars, and several Facsimile Reprints in Herpetology. Members may purchase other Society publications at reduced rates.

ANNUAL DUES



Student member	$10.00
Regular member	$12.00
Sustaining member	$20.00
Contributing member . . .	$25.00
Institutional	$20.00

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of the SSAR. For information about SSAR membership, write to:

Host

ARIZONA STATE UNIVERSITY

Tempe, Arizona

31 May - 7 June 1978

31 May Wed - Registration begins + Society Board Meetings

1 June Thu - Contributed papers + Regional Societies Herp Conference (SSAR)

2 June Fri - Contributed papers + Symposium: Anuran Social Behavior (ASIH) + picnic

3 June Sat - Contributed papers + Amphibian Metamorphosis Conference
3 June Sat - Symposium: Herpetology in western North America (HL) + Social

4 June Sun - Field Trips

5 June Mon - Symposium: Biology of Damselfishes (ASIH)
5 June Mon - Symposium: Reproductive Biology of Captive Reptiles (SSAR)

6 June Tue - Symposium: Biology of Damselfishes (ASIH)
6 June Tue - Symposium: Reproductive Biology of Captive Reptiles (SSAR) + Banquet

7 June Wed - Special trips by arrangement, if sufficient interest.

GENERAL INFORMATION:

Pre-registration forms, including Call for Papers and other information, will be mailed to Society members in February. Copies will be sent on request to interested persons. Air-conditioned dormitories will be availale. Limited camping facilities will be available near Tempe.

Transportation: Air travelers should make reservations to Phoenix Sky Harbor International Airport. Economical limousine service is available from airport to campus or Tempe motels, or local committee will provide free transportation to and from airport if notified in advance of carrier and arrival or departure times.

Local Committee Chairman: M. J. Fouquette, Department of Zoology
Arizona State University, Tempe, AZ 85281
(602) 965-5070

Herpetology at Arizona State University

Arizona State University was established in 1885 in the town of Tempe, as the Territorial Normal School. Bills establishing both the school at Tempe and its sister institution in Tucson were signed the same day. When Arizona achieved statehood, in 1912, the name had become Tempe Normal School. In 1925, it became Tempe Teachers College, with a four-year curriculum, offering one degree, a Bachelor's in Education. In 1929, the school was further upgraded and the name was changed to Arizona State Teachers College at Tempe. In 1945, it became Arizona State College at Tempe and offered degrees in Liberal Arts, as well as education. The greatest enrollment seen at the modest institution up to that time was 882. Following World War II, enrollments began to rise dramatically. In 1949 over 4000 students were registered. In 1947, the name "Sun Devils" was adopted for the athletic teams, replacing the former "Bulldogs". In 1954, the institution was reorganized along university lines to include four colleges, but for political reasons the name remained Arizona State College. In 1958, the political barrier was broken by an unprecedented public referendum, with a 72% voter turnout, and the name Arizona State University was adopted by a 2 to 1 margin. In the 1977-78 academic year, ASU is the largest university in the state, with a registration well over 35,000.

Most of the buildings on the main campus (566 acres; Fig. 1) are less than 20 years old, but some of the older buildings remain. The Hayden Library houses over 1 1/2 million volumes (including a fine collection of classic and current herpetological literature). Other buildings include the modernistic, 3000-seat Gammage Auditorium (Fig. 2; last design of Frank Lloyd Wright), a large, well-equipped Memorial Union, and a 59,000-seat athletic stadium (currently being enlarged). There is an excellent art collection and a photographic gallery. The university also operates a PBS-affiliated television station, serving the Greater Phoenix area, along with five commercial TV stations. Off-campus, the university operates a field laboratory (experimental farm) on 320 acres near the main campus, and a continuing education facility (Camp Tontozona) near Payson, Arizona.

There are 11 colleges plus several special divisions and services. The Graduate College offers 13 Masters and three Doctoral degrees; included are the Master of Arts and Master of Science in 36 majors, and the Doctor of Philosophy in 17 majors (including zoology). Over 9000 students are currently enrolled in the Graduate School.

Figure 1. Aerial view of the main campus, Arizona State University.

The Department of Zoology is housed in the Life Sciences Center (over 150,000 sq. ft.), which it shares with the Department of Botany-Microbiology. About 62,000 sq. ft. are allotted to Zoology; over 4500 sq. ft. house systematic collections (herps, fishes, birds, mammals, insects, mollusc shells); 4000 sq. ft. are included in the Animal Resource Center. The new 7-level west wing (Fig. 3) contains many modern facilities, including an electron microscopy laboratory with both transmission and scanning instruments. Currently, Zoology has 32 faculty members. Research interests are strongest in ecology, but expertise in all areas of biology is well represented both in terms of research and course offerings. There are about 550 undergraduate majors in zoology and about 80 graduate (50 M.S., 30 Ph.D.). Department chairman is Dr. Ronald Alvarado, whose research is on ionic regulation in amphibians. Dr. M.J. Fouquette works primarily on anuran systematics and ecology (particularly bioacoustical aspects), and in other areas of environmental and systematic herpetology. His research is currently supported by a grant from the National Science Foundation and focuses on testing of reproductive and ecological character displacement among anurans, particularly spadefoot toads. He is also completing studies of South American treefrogs and southeastern U.S. chorus frogs. Dr. Fouquette has responsibility for the herpetological collection of approximately 20,000 specimens. Dr. James Collins is an ecologist who has studied evolution of life history patterns in anurans. Currently he is investigating environmental factors selecting for carnivorous morphs in Scaphiopus larvae, and environmental pressures influencing neoteny in Ambystoma tigrinum.

Research of several other members of the Zoology faculty bears on herpetology. Dr. Neil Hadley, an environmental physiologist, has studied bioenergetics of lizards in desert ecosystems, and the role of lizard and anuran integuments in water loss. Dr. Jerry Justus, a developmental biologist, is supported by a grant from the American Heart Association to study heart development and developmental genetics in the Axolotl, and also studies developmental rates in Scaphiopus and metamorphosis in Ambystoma tigrinum. Dr. Robert Ohmart directs the wildlife biology program and has interests in physiological ecology and ornithology, and has also done some ecological studies on herps, including a current program on the desert tortoise involving several

Figure 2. Grandy Gammage Auditorium.

Figure 3. Life Science Center, west wing.

graduate students. Dr. "Mink" Minckley is primarily an ichthyologist, but his studies have included work on reptiles and amphibians, especially in the Cuatro Cienegas region of Coahuila. Dr. Herbert Stahnke is retired and Professor Emeritus; he is known for pioneering application of cryotherapy to treatment of poisonous snake bite.

The Department of Zoology also has the endowed Maytag Chair in Vertebrate Zoology. Each year an outstanding vertebrate zoologist is invited to fill the Chair and offer a course or seminar, primarily to enhance the graduate program. Maytag Professors, from 1971, have been Ernst Mayr, Donald Tinkle, E. Raymond Hall, Robert Briggs, John Emlen, Allen Stokes, and Steve Fretwell. C. Ladd Prosser is Maytag Professor for Spring 1978, and James R. King will be Maytag Professor in Spring 1979.

Some recent recipients of graduate degrees in Zoology, involving herpetological thesis research, include: Laurie Vitt (Ph.D., 1976; lizard reproductive effort; currently on postdoctoral fellowship with P. Vanzolini in Brazil); Richard Van Loben Sels (M.S., 1976; reproductive ecology in Urosaurus; currently teaching high school in Phoenix); Joseph Mitchell (M.S., 1976; ecology of uniparental and biparental Cnemidophorus; now in Ph.D. program at Univ. of Tennessee); Nancy Dickson (M.S., 1976; hunting behavior in Hypsiglena); Marc Willner (M.S., 1977; numerical taxonomy of Bufo); Justin Congdon (Ph.D., 1977; bioenergetics of Sceloporus jarrovi; now on postdoctoral fellowship, Univ. of Michigan).

Some current graduate students with herpetological thesis projects include Maurice Renaud (Ph.D., systematic variation in Hyla wrightorum), Steve Wylie (Ph.D., ecology and behavioral thermo-regulation in Hyla arenicolor), Billy Jean Grounds (Ph.D., enzyme variation in uniparental and biparental Cnemidophorus), Judd Howell (Ph.D., effect of Rana pipiens larvae on algal communities), Tim Stevens (M.S., ecology of montane Cnemidophorus), Jamie Jenkins (M.S., post-feeding behavior in geckos), Dan Strecker (M.S., tapeworm infections in Coleonyx), Carl Price (M.S., karyotypic comparison of crotaline snakes), James Schwartzman (M.S., biotelemetry and ecology of Gopherus), Lauren Porzer (M.S., behavioral and physiological ecology of Heloderma), Judy Hohman (M.S., field studies of Desert Tortoises), Barbara Ewan (M.S., ultrastructure of developing axolotl heart muscle), and Robert Knox (M.S., physiological study of Rana catesbeiana larvae).

Arizona State University is in the city of Tempe (pop. 100,000). Tempe and the adjacent cities of Mesa and Scottsdale (also about 100,000 each) adjoin the east side of Phoenix (pop. over 1,000,000) and together comprise the main population center of Arizona. These cities lie in the Sonoran Desert in the Salt River Valley ("Valley of the Sun") of south-central Arizona, elevation about 500 m. The Phoenix Zoo is about 3 miles from campus. Phoenix Sky Harbor airport is within about 5 miles of the campus. Indian ruins, museums, recreational lakes (swimming, fishing, boating) and mountains are nearby. A bit farther are Flagstaff (150 miles) with Northern Arizona University and the Museum of Northern Arizona, the Grand Canyon (220 mi), Tucson (110 mi) with the University of Arizona and the Arizona-Sonora Desert Museums, and Mexico (Nogales, 175 mi).

Arizona State University and the Department of Zoology will host the joint annual meetings of the Society for the Study of Amphibians and Reptiles, the Herpetologists' League, and the American Society of Ichthyologists and Herpetologists, May 31-June 7, 1978.

M.J. FOUQUETTE, JR., Department of Zoology, Arizona State University, Tempe, Arizona 85281.

MUSEUM ACRONYMS

Prepared by
Electronic Data Processing Subcommittee
Herpetological Resources Committee

The Electronic Data Processing Subcommittee of the Herpetological Resources Committee is recommending the adoption of a standard set of acronyms to be used in citing museum specimens in technical publications. The Subcommittee has compiled a list of the world's museums and other research centers with holdings of amphibians and reptiles. It has also compiled a list of acronyms for each of these collections, drawn from the literature, from its own experience and from suggestions offered by colleagues.

In preparing the list that follows, the Subcommittee has been conservative, making few changes in the "accepted" list of acronyms, i.e. those of long-standing and which have appeared most frequently in the literature. In a few instances the Subcommittee has taken upon itself the responsibility of altering established acronyms where duplications between institutions exist. The following criteria have been applied in the selection of acronyms: 1) wherever possible the most commonly used current acronym has been retained [with attention being given to the selection of the most appropriate acronym among several alternatives that appear to be in current use for a single institution]; 2) in the event of acronym duplication, preference has been given to the retention of the acronym of the institution whose resources have been utilized more broadly and cited in the literature most frequently; 3) where modifications of existing acronyms were deemed necessary, the changes usually were limited to the addition of a single alpha-character to the end of the established acronym, the single character in most instances representing the first letter in the name of the city where the collection is housed.

During the last few years, several important collections of long-standing have been merged with other collections. For instance, the herpetological resources formerly maintained at Stanford University were transferred to the California Academy of Sciences where they are now permanently stored. Because the Stanford collections were frequently cited in the literature, its acronym is listed. An *'(X)'* follows the name of the institution, an indication that the collections are no longer at Stanford, having been transferred to one or more active resource centers. In a few cases a *'(Y)'* follows an institution's name, indicating a change in title only. Ownership and administration of the collections remain with the organization (e.g. the Chicago-based Field Museum of Natural History was formerly known by the name Chicago Natural History Museum).

The Subcommittee has tried to be consistent and changes have not been made without cause. Inasmuch as this list is presented here for comments and criticisms by the herpetological community, it should not be adopted as the final recommendation of the Subcommittee. Rather, your comments, including additions to the list, are solicited so that the Subcommittee can submit a final report that represents the consensus of the user community. Penultimately, although the preliminary report submitted herein for your perusal is not cross-indexed, the Subcommittee will include a cross-index in its final presentation. The cross-index will permit location of an acronym by institution, or visa versa, as well as by country and city.

Should you, as a potential user of this reference list, or as an individual directly concerned with any institution mentioned, wish to recommend emendations or additions, or have comments that would enable the Subcommittee to improve its presentation, please address your remarks to: *Dr. A. Leviton, California Academy of Sciences, San Francisco, California 94118 (USA).*

For the Subcommittee:
William E. Duellman
Tom Fritts
Alan E. Leviton

Evidence for Species Specificity of Pheromone Trails in Two Sympatric Garter Snakes, Thamnophis

Pheromone trails are used by social and semisocial animals to form aggregations for purposes of breeding, feeding or controlling environmental factors (e.g., humidity). In the cases of reproductive and feeding aggregations, it would be advantagious to a species to form a group of only conspecifics. The trail laid by an animal for these functions should therefore be species specific. Blum and his coworkers have recently examined trail followings in the social insects and have found that several species of ants and termites do show preference for conspecific trails (Barlin, et al., 1976; Blum, 1974). Trailing in snakes for purposes of reproduction or aggregation has been reported often in the literature (for review see Burghardt, 1970; Ford, 1976). Species specific mate selection does occur in snakes (Devine, 1976), however, no studies on species specificity of ophidian pheromone trails have been conducted.

While examining the mechanism and seasonality of trailing behavior in the western ribbon snake, Thamnophis proximus, and the red-sided garter snake, T. sirtalis, in Oklahoma (Ford, 1976), I found that these sympatric species showed little interest in each others females' trails. In view of the nature of these responses, a behavioral bioassay for species specificity of the trails was developed. Since I felt that a simple "Y" maze was not suitable due to the limited number of experimental animals available, a multi-choice (five-armed) test chamber (Fig. 1) was constructed. Ten tests utilizing four adult T. sirtalis males were conducted at the University of Oklahoma Animal Behavior Laboratory in June and October of 1975 (these months were active trailing periods; Ford, 1976). For each test, the following procedure was carried out:

1. The male to be tested was confined in box A two hours previous to the test (all letters refer to Fig. 1).

2. A conspecific and a heterospecific (one adult T. sirtalis and one adult T. proximus) female trail were laid on a fresh sheet of butcher's paper. Trails were prepared by inducing each female to crawl through a 14 cm wide bottomless tunnel placed on the paper.

3. The choice chamber was then placed on the paper so that each trail led from the opening in front of holding box A, into one of the five arms of the chamber. The arms to which each of the two trails led were chosen at random for each test.

4. Trapdoor B was then opened and the male allowed access to the chamber. The male could upon entering the chamber follow the conspecific's trail, the heterospecific's trail, or enter one of the three blank arms. One-way aluminum doors (C) trapped the male in the first arm he entered. The arms were checked after four hours and the location of the male recorded.

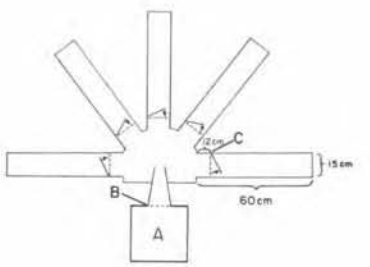

Figure 1. Multi-choice Test Chamber for Species Specificity of Thamnophis Pheromone trails. (A) removable holding box for male. (B) trap-door. (C) light weight aluminum one-way swinging doors (hanging from top, not the side as shown). The apparatus has no bottom and is positioned on a new sheet of butcher paper for each test.

Thamnophis proximus and T. sirtalis males chose arms with conspecific females' trails leading to them in 50% of the tests (Table I). If preferential selection of the arms did not occur, the males would be expected to end up in the conspecific arm 20% of the time (statistical tests were not conducted due to the low sample size). This does suggest that a preference for conspecific trails occurs in these two species in Oklahoma. In this study, 60% of the animals tested were found in arms with trails. In 85 observations of T. proximus and T. sirtalis in other trailing experiments (Ford, 1976), I found that during the active trailing months, males would follow the female's trail only 50 to 80% of the time. If choice chamber tests in which the male chose a blank arm are ignored here (the 40% expected nontrailers), then the males chose the arm with the conspecific trail in 83.3% of the trials. This supports even more strongly the species specific nature of these pheromone trails.

Test ♂ / Arm Choice	T. sirtalis	T. proximus
Conspecific ♀ trail	5	5
Hetero-specific ♀ trail	1	1
Blank (3 arms)	4	4

Table I. Trail Preference of Thamnophis Males in Multi-choice Test Chamber.

The western ribbon snake and the red-sided garter snake are sympatric in Oklahoma and are found in the same general habitat. If, as most observers of snake trailing behavior believe, the trail functions to guide the male to the female for breeding, it would be adaptive for the pheromone involved to be species specific. Males could thereby restrict their trailing to only females of their own species. This study is the first evidence of this species specificity of snake pheromone trails.

Litter Size and Parturition Behavior in Sistrurus miliarius streckeri

Klauber (1956) reported on 15 "egg-sets" or "broods" of Sistrurus miliarius barbouri, ranging in number from 2 to 18 ($\bar{x}$=7.33±1.05), 2 of S.m. miliarius of 3 and 9, and 4 of S.m. streckeri of 4, 6, 6 and 7. Sabath and Worthington (1959) reported a S.m. streckeri bearing 5 young on 31 July. Carpenter (1960) recorded an unusually large litter of 32 born on 6 August. Clark (1963) reported on a litter of 3 male and 2 female S.m. streckeri born on 9 July. Finally Palmer and Williamson (1971) in their study of S.m. miliarius, reported length data for litters of 7 (n=1), 6 (2), 5 (8) and 4 (3) young born between 11 August and 8 September. Only Carpenter (1960) discussed parturition behavior. Herein we present length-weight data for two litters of S.m. streckeri and a detailed account of parturition behavior of one female and her offspring.

In the first instance, a gravid S.m. streckeri (SV=325 mm), Total length=380 mm, Wt=42 g) captured in Sabine Co., Texas on 23 August 1974 gave birth to 5 living young the following night. Neonates were measured and then preserved in the Stephen F. Austin State University Wildlife Collection. These young were the smallest neonates heretofore recorded (SV=95 mm, TL=102 mm; 98, 104; 95, 102; 92, 102; 98, 103).

A second S.m. streckeri (SV=355 mm, TL=410 mm, Wt=36.6 g) was observed in a loblolly-shortleaf pine (Pinus echinata and P. taeda) forest in Nacogdoches Co., Texas on 1 July 1976. This female was subsequently observed on 7 occasions within 2 m of its original location until 3 August, at which time she was taken to the laboratory. Between capture and parturition, she ate one adult ground skink (Scincella laterale). On 23 August, she produced a litter of 5, of which 2 were born dead (SV=140 mm, TL=161 mm, Wt=2.8 g; 141, 161, 2.5; 140, 158, 2.7; 125, 143, 1.6; 123, 141, 2.1). The two dead young were smaller than their living siblings and retained part of the external yolk sac.

The female was observed at 1804 hrs. with the first fetal sac partially protruding from her cloaca; it fully emerged one minute later. Young 2, 3, 4 and 5 were born 49, 30, 25 and 80 min. apart, respectively. The female remained coiled during labor and each birth was characterized by a series of from 8-19 undulatory contractions. These peristaltic contractions passed caudad through the posterior two-thirds of the female's body, generally beginning 2-5 min. apart and ending about 10 sec. apart. During contractions, the fetal bulge could be seen to move caudad. Near the end of the undulatory series, there was a series of up to five convulsive cloacal contractions and elevation of the tail. This was followed by emergence of the fetal sac which in three timed instances required 4, 3 and 3 min. Young moved their heads vertically and uncoiled from within the membranes. Subsequently, two young moved their heads from side to side in scraping movements against the female's body which lasted up to 25 sec. and continued at irregular intervals for 16 to 26 min. This behavior may remove mucus and debris from the mouth or loosen the natal skin. The fifth neonate had the shortest time between parturition and shedding and did not exhibit this behavior. Interspersed with the scraping behavior, the young gaped their jaws (1-4 times each) into a yawn-like position.

The female jerked, recoiled and occasionally lifted a coil slightly as the neonates touched her. Following scraping and yawning behavior, the neonates crawled out of the female's coil to other parts of the terrarium. After birth of the last young, the female uncoiled and for a 30 min. period crawled to approximately 5 cm of each living young several times and appeared to examine it by tongue flicking. She demonstrated no reaction to the two dead neonates.

Sloughing of natal skins required about two minutes subsequent to the skin being loosened around the head. Completion times for ecdysis were: 1 hr. 48 min. post-parturition for neonate number 2; 2 hr. 55 min. for number 3; and 1 hr. 35 min. for number 5.

A Note on the Defensive Posturing of Turtles From Belize, Central America

Although there are considerable data available on various aspects of the behaviour of turtles, little has been published concerning the postures assumed by turtles when confronted by a predator. Dodd and Brodie (1975) have provided a brief review of turtle defensive behaviour and illustrated defensive posturing by the snapping turtle, Chelydra serpentina.

While in Belize, Central America, I had the opportunity to observe defensive posturing by several species of turtles. The first instance occurred 50 km northwest of Belize City on the road between the Northern Highway and the Altun Ha archaeological site and involved a Claudius angustatus (115 mm) crossing the road. Immediately upon my approach, the turtle leaned in my direction such that the carapace was directed at me. The legs and head were kept under the shell, and the posture was maintained by extension of both front and rear legs; the tail was not used to maintain balance as has been reported for Chelydra serpentina (Dodd and Brodie, 1975). When tapped on the frong or rear of the shell, the turtle redirected its posture toward the stimulus such that the carapace was always directed at it. While maintaining the posture, several very quick upward biting lunges were attempted. After several minutes of harassment, the turtle abandoned the posture and ran very rapidly in an attempt to gain cover. However, when its path was blocked, the posture was again assumed.

The second instance of posturing involved a Rhinoclemys areolata (110 mm) kept as a pet. When tapped on the side, this turtle also leaned in the direction of stimulation and vigorously used its rear legs to maintain balance and, if necessary, change direction. The head and front legs were kept well under the margin of the carapace and no biting attempts were made. Unlike the Claudius, the front legs were not used to maintain the posture when the turtle was tapped from the side; when tapped from the rear, the turtle ran instead of postured.

As a generality, the posturing observed in Claudius angustatus and Rhinoclemys areolata is similar to that of Chelydra serpentina (Dodd and Brodie, 1975), Chelys fimbriata (Neill, 1971), and Platysternon megacephalum (Pope, 1935). As Dodd and Brodie (1975) point out, many animals are known to expose a particular defensive surface to direct contact with a potential predator; it would appear that many species of turtles representing a number of families do likewise by directing the carapace toward the predator and drawing in the head and limbs beneath the shell. However, some species, such as Claudius angustatus and Chelydra serpentina, have added a sudden vicious biting lunge to their defensive repertoire. By having the head concealed under the carapace and suddenly thrusting it out and attempting to bite, the turtle may effectively injure a predator or at least startle it. Presumably, the possibility of being bitten would discourage a predator in future contacts with a posturing turtle.

ACKNOWLEDGMENTS

I would like to thank Mr. Tom Shaw for allowing me to observe the Rhinoclemys areolata and George Zug (National Museum of Natural History) for aiding in the identification of the turtles.

Book Reviews

NORTH AMERICAN HERPETOLOGY, by John Edwards Holbrook. Society for the Study of Amphibians and Reptiles. 1976. xlix, 682 pp., 147 pls. (20 in color), clothbound. $60 (postpaid anywhere in the world from Dr. Douglas H. Taylor, Dept. Zoology, Miami Univ., Oxford, Ohio 45056).

Accustomed to a steadily intensifying information explosion over the past few decades, leading to dependence largely or entirely upon the most recent work as authority, most herpetologists are, either secretly or openly, likely to view the monumental reprint of Holbrook's second edition (1842) of North American Herpetology as of dubious significance. After all, so few have ever seen a copy of either edition, or had ready access to it, that perforce it was consigned to the oblivion that all exceedingly rare works share. And no doubt a goodly number of those who obtain a copy of the reprint do so more for its value as a collector's item than for its content.

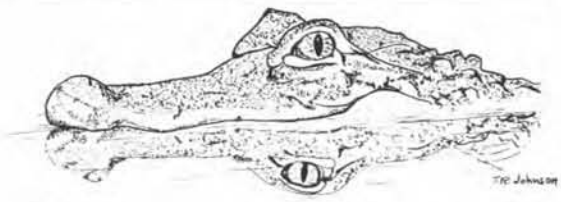
A collector's item it is, without doubt, for it is a superbly executed reproduction of a monograph that itself set standards far beyond those of its time, and the original has been so rare as to command a price of $4000 in recent years. Attending for the moment to the workmanship of the reprint, it is an oversize (8.5 x 11 in., 21.5 x 28 cm) volume, 2.5 in (63 mm) thick, containing a reproduction of all 5 original volumes, including all of their 147 plates. By careful screening of a dozen or so copies of the original edition by the editor, Kraig Adler, the reprint includes all errata and additions noted in any of them, and in this respect is more complete than any one copy of the original, inasmuch as very few copies of the original are identical in all respects. The reprint differs from the original in having slightly smaller margins (although plates and text are of exactly original size), and in having most plates reproduced in black-and-white instead of color. However, 19 of the best plates representing all 5 volumes and all 5 major groups of herpetozoa (anurans, salamanders, turtles, lizards, snakes) were carefully selected for color reproduction. The paper is acid-free for maximum longevity (several centuries), and the whole is sewn and durably bound in library buckram.

The reprint was issued in 2 editions, totalling 1000 copies: 890 in the "regular" edition (some still available at this writing), and 110 in a "patron's" edition available only by advance subscription ($175). The latter is exquisitely bound. No expense was spared to make it match the style of Holbrook's original--no easy task today in America where binding by hand is virtually a lost art. Two of the most eminent book craftsmen in America (Trudi and Fritz Eberhardt, who, among many other honors, were commissioned to bind presentation sets of books given by U.S. officials to the Vatican, Queen Elizabeth II, Mao Tse-Tung and Chou En-Lai) were engaged to produce a binding with scarlet-red morocco leather spine and covers over genuine hand-marbled boards with 23-karat gold top edge and ornamentation (pure gold is not suitable for bindings intended for maximum endurance). In addition all patron's copies were accompanied by an unbound portfolio containing a set of all the color plates printed on oversize (10 x 13 in., 25.5 x 33 cm) sheets of heavy stock suitable for framing. Each book also is bound with a numbered colophon page bearing the signatures of the authors of the introductory sections.

Magnificent though the patron's edition certainly is, the workmanship in both editions is abslutely superb and a monumental credit to the notoriously meticulous skill of its editor.

A final touch of masterful planning scheduled the appearance of the reprint during the Bicentennial celebration, thereby constituting one of the more effulgent events of that year. It should be a matter of record that, although the patron's copies were not bound and mailed until 1977, the first copies of the regular edition were distributed in 1976, establishing that as the publication date.

The new introductory section of 49 pages conforms completely with the standards of excellence set elsewhere in the reprint edition. It includes a frontispiece of a color portrait of Holbrook by the deservedly and increasingly noted young artist David M. Dennis, designed as a collage especially for the reprint (a signed, dated and numbered copy is included in the unbound portfolio of the patron's version). A 3-page "Editor's Note" provides a background for the undertaking, with acknowledgments. A list of subscribers follows, constituting a sort of Who's Who in American herpetology: 90 individuals, excluding 3 from the Eastern hemisphere and 9 institutions or their libraries. A superb 15-page account of Holbrook's life and writings follows, by Richard D and Patricia H. Worthington. Another 15 pages are devoted to an analysis by Kraig Adler of all new taxa (39) described and named in all editions of Holbrook's 'North American Herpetology', giving the proper source citation, type-locality and location



of types for each, often with illuminating notes. The introduction terminates with a 5-page tabular summary of the "Current Nomenclature for Scientifc Names in Holbrook's North American Herpetology including a Table of Contents," by Richard D. Worthington. A total of 150 species-group names used by Holbrook are dealt with.

In some ways the reprint is content-wise far more useful than a copy of one of the original editions, for it not only combines in one volume the textual variants of several original copies, but the introduction is an invaluable digest of all of the original editions. Because each copy of the original editions is unique (individually hand-painted and many bearing small variants of the text), the reprint is not likely to diminish the value of any. It is, however, a virtually essential complement, nd it makes this great work now readily accessible for any serious student, performing for American herpetology what Martin Luther did, in reference to the Bible, for the Christian world: making a basic work previously monopolized by the privileged few available to the common man.

Because of the general accessibility of Holbrook's monograph provided by this reprint, herpetologists in general--not only the "privileged few"--can appreciate the extraordinary degree to which Holbrook was ahead of his time. Had the work been widely available it might have had a very salutary effect upon herpetological practices of the latter half of the 19th century, because in Holbrook's time, and before, descriptive herpetology was for the most part extremely superficial, and it remained so until near the turn of the century. Holbrook's work, on the contrary, was far superior, providing detail that was not widely recognized as essential until well into the 20th century. Had his monograph been widely accessible and readily consulted, his meticulous work might have been more widely influential. His care in nomenclatural usage was also exceptionally exemplary for his time. The conclusion cannot be escaped that in herpetology he was an intellectual giant in his era, certainly not approached by any other American worker. Rather like Leonardo da Vinci, unfortunately, the full extent of his genius was not widely appreciated for many years, and indeed never would have been so without the appearance of this popular, annotated edition of his greatest work.

So dedicated have been the efforts of so many individuals to make this reprint perhaps the most notable publication event in herpetology of this century, that it is very difficult to envision any way in which it could have been improved. It approaches very near absolute editorial perfection. In matters of style, it might have been preferred that the nomenclatural rule had been followed of enclosure of an author's name in parentheses after the name of species using a generic name other than the original; or that the policy adopted in the International Code of Zoological Nomenclature, of hyphenation of all combinations of "type" (e.g. type-locality, type-specimen, etc.) had been followed. These are essentially subjective and quite insignificant reservations.

In sober consideration of the significance of this event, it is apparent that the superficially

formidable price of $60 is in reality an exceptional bargain and it behooves any serious student of North American herpetology to take advantage of it while he can. Every herpetological library of institutional caliber anywhere in the world would benefit by possession of a copy.

HOBART M. SMITH, Department of Environmental, Population and Organismic Biology, University of Colorado, Boulder, Colorado 80309.

ONTOGENY AND PHYLOGENY by Stephen J. Gould. 1977. The Belknap Press of Harvard University Press, Cambridge, Massachusetts. ix + 501 pp., illus. $18.50.

Every year when I ask my freshman zoology class, "Who has heard the phrase 'Ontogeny recapitulates Phylogeny'?" most students raise a hand. I then ask whether their high school biology teachers presented this slogan as "true" or "false." About as many students indicate "true" as "false." This interrogation leads into a class discussion of Haeckel's famous principle. The class comes to believe that there may be some vague truth to the Haeckelian declaration but that it doesn't stand up as an invariant law of evolution. The students may learn something from this exercise but I come away each year feeling like something is lacking (besides quality education in high school).

Things should be better this year thanks to Steve Gould's new book Ontogeny and Phylogeny. Gould reviews, clarifies and interrelates such important concepts as recapitulation, heterochrony, paedomorphosis and neoteny.

Ontogeny and Phylogeny is really two books. The first one of approximately 200 pages reviews the history of the recapitulation concept from before Aristotle to the beginning of this century. The second book, of equal length, starts with an examination (and a rejection) of de Beer's (1940) classification of the products of heterochrony. The body of the second book is a presentation of Gould's own ecological perspective on heterochrony. The last chapter affirms the role of neoteny in the evolution of man.

The remaining pages consist of chapter by chapter footnotes (26 pages worth), a bibliography (circa 850 references!), a topical glossary of some hundred terms pertaining to ontogeny and phylogeny, and an index.

The book is far more than the above summary or book title indicates. Gould documents, in his own words (p. 6) "the decisive influence that recapitulation has had on non-biological areas as disparate as racism and Freudian analysis" in order to "convince some scientists (an unnamed sociobiologist comes to mind) that the arcane researches of cloistered academics may be full of social significance, and that scientific detachment and absolute objectivity are myths." Gould makes no effort to be subtle in his condemnation of biological determinism.

In the latter half of the book. Gould makes several important biological distinctions. Heterochrony (acceleration or retardation of the development of one organ system in relation to another) produces parallels between ontogeny and phylogeny. Depending on what is retarded and what is accelerated the morphological result may be recapitulation, or paedomorphosis. Both progenesis (=De Beer's "paedogenesis"--Gould prefers progenesis for historical reasons) and neoteny come under the heading of "paedomorphosis." In the former case, the growth of somatic features is retarded, while in the latter case, the maturation of reproductive organs is accelerated. Gould shows that this is no trivial difference. Using pages of examples, Gould demonstrates that progenesis is regularly associated with miniaturization, short generation times and rapid rates of population growth (r-selection in the parlance of population biology). Neoteny, in contrast, is usually associated with adaptations for maintenance of individuals near environmental carrying capacity (K-selection). The slow development

of neotenous individuals is just such a K-selected adaptation. Although Stearns (1976) cautions us against the casual application of r-K selection, Gould builds an extremely well documented case. His insight into the importance of heterochrony on life history strategies is, to me, the most valuable part of this book. Finally someone has provided a consistent and ecologically meaningful distinction between paedogenesis and neoteny.

In a short concise epilogue Gould links his whole story to that of regulatory genetics. Heterochrony can account for enormous morphological differences between ancestor and descendent by slight differences in the expression of a few regulator genes. Rapid morphological evolution with a miniscule modification of the genome--this, Gould believes, is the "major stuff of evolutionary change" (p. 409).

By now you may have decided that this ambitious book has little to do with the refined discipline of herpetology. On the contrary, amphibians receive extensive coverage in Ontogeny and Phylogeny. The axolotl initially rose to fame when presented as evidence against recapitulation. Gould argues that something so atavistic as this adult Ambystoma with gills nevertheless failed to sway 19th century proponents of recapitulation; along the way he reviews much of the early literature on artificial metamorphosis of salamanders. Perennibranchiate salamanders are presented as ideal examples of K-selected neotenic animals. The works of Sprules (1974a,b) on Ambystoma and Wake (1966) on plethodontids are discussed in detail. Although Gould is not a herpetologist he has established strong communications with herpetologists. His terminology makes good herpetological sense and is likely to be used by workers in our field.

My major regret about this book is that it is longer than it need be. It is repetitive, with hundreds of conversational asides that break up the flow. I fould myself becoming frustrated by the constant need to flip to the back of the book to track down notes. Many of the notes are not essential and only appear because the language of some German author appealed to Gould's poetic sense.

The same erudition and witty verbal constructions that make Gould's column ("This View of Life") in Natural History a delight to read begin to appear self-indulgent when unconfined by space limitations. Gould loves to turn a phrase. His new perspectives may reveal delicate features of a subject and give it depth, but they can obscure the overall view.

This is a book too important to be buried in libraries under its own weight. Hopefully a shorter version will appear. While this suggestion may offend the purists, I do not believe that the shorter versions of the works by Ernst Mayr, G.G. Simpson and D'Arcy Thompson, for example, hurt their causes. Gould's contributions to the fields of functional morphology and evolutionary biology rank with the contributions of Thompson, Mayr and Simpson to their respective fields. His work deserves equal exposure.

Herpetological Husbandry

The Captive Care of Hatchling Tortoises

In general, the captive rearing of newborn reptiles is difficult and often exasperating. More specifically, hatchling tortoises often present the herpetologist, whether amateur or professional, with husbandry problems that must be solved in order to insure the survival of these chelonians.

One can group certain problems imposed by captivity as follows: 1) improper cage substrate; 2) constipation; 3) eye disorders; 4) temperature regulation.

For seven years, twenty-three hatchling tortoises belonging to the genus Gopherus, and several specimens of Geochelone chilensis have been successfully grown to the adolescent stage with no hatchling mortality. The step-by-step procedure and the solutions to the above listed problems, which lead to instant success, are here presented.

Cage Substrate: It has been found that all inorganic substrates are undesirable and usually lead to 100% hatchling mortality within 18 months. Death is caused by intestinal impaction, and can be diagnosed by a tortoise that is heavy but not feeding for a prolonged period.

Solution: A plant fiber substrate known as "Litter Green" can be purchased at any grocery store and will provide the ideal cage flooring. if the small pellets are ingested they are easily digested with no resulting impaction. One inch of litter is sufficient to create good traction and absorption of fluids.

Constipation: The most common cause of death in newborn terrestrial chelonians, in captivity, is constipation. This can be caused by ingestion of sand or gravel cage substrates or by improper diet.

Solution: Prepare a pan of lukewarm water that will allow the tortoises to get air without difficulty. Place the hatchlings individually in the bath for soaking and drinking. This procedure should be followed every week during their first year, whether or not constipation is suspected. Soaking tortoises is one of the most useful procedures to prevent beginning constipation problems and of course for metabolic needs. Immediately after a hatchling drinks for a few minutes, it will have a bowel movement composed mainly of uric acid. This flushing out of its system works very nicely, and keeps the eyes free of particles.

Eye Disorders: Swollen eyes and loose skin around the eyes may be the result of inadequate diet--the lack of vitamin A.

Solution: The following diet should be used for all desert or Mediterranean species: 40% leafy romaine lettuce; 40% raw spinach leaves; 5% chopped apple; 5% grated carrot or tomato, with tricalciumphosphate mixed in for vitamin-mineral supplementation. The salad can be sprayed, lightly, with water to allow the tricalciumphosphate to adhere to the leafy material. This provides a good reliable diet, which is readily accepted by the tortoises. The hatchlings should be fed daily as much as they can consume.

Temperature Regulation: The whole key to any reptile's survival is proper environment. Many reptiles fare better if exposed to a mild temperature drop from day to night. These types of tortoises fall into this group, so the keeper will want to satisfy this important requirement.

Solution: A group of tortoises, up to ten hatchlings, can be best housed in a ten gallon size glass aquarium. The tank should be equipped with a clamp-on light socket and a 60 watt bulb. This should be mounted at one end of the cage, so that the youngsters can move away from the heat source if need be. This cage set-up must be in a building or room that is maintained between 70-75 F during the day; the bulb should be set so that it is 5-6" above the organic substrate. The daily temperature drop is accomplished merely by turning off the light for the evening. The lamp is then turned back on in the morning. An inexpensive 24 hour automatic timer can be installed for the more absent-minded keeper. No top is needed over the tank, unless the room is maintained below 70 F during the day. The temperature should not drop lower than 60 F at night and the daily variation should not exceed a range of 25 F.

Tortoises of the genus Gopherus have grown to a length of 4-5" (carapace straight line measurement) during the first year following this type of husbandry procedure. Specimens exhibiting pyramidal shape of the dorsal laminae do so because of excessive growth.

One may wonder why inorganic substrates should be avoided, when these animals live in the wild on sand, dirt, and gravel-like areas. All too often, people believe that they are duplicating a natural situation in captivity, when, in fact, the effort is very unnatural and detrimental to the captive. Tortoises feeding in the wild are not exposed to food items that are dropped on the ground while still moist as in captivity, nor are they ingesting large quantities of debris with their daily feedings. When a person placed a hatchling tortoise on sand, this substrate sticks to the food and is consumed during feeding; this eventually causes the death of the chelonians.

In summary, a keeper will find that a ten gallon aquarium filled with plant fiber litter and heated by a 60 watt light bulb will easily keep a herd of hatchlings thriving after their weekly "swim" and soak sessions.

Products mentioned in the article: LITTER GREEN, 100% alfalfa pellets, manufactured by McFadden Company, 6901 West 63rd Street, Overland Park, Kansas 66202.

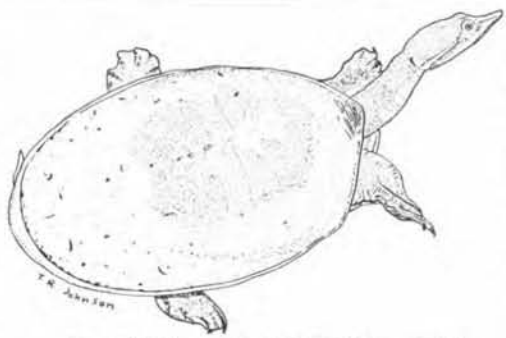
Some Aspects of Breeding and Raising Aquatic Chelonians: Part I

In the past two decades, there have been several noteworthy publications on chelonians (Wermuth and Mertens, 1961; Pritchard, 1967, Ernst and Barbour, 1972; Conant, 1975), but most have been primarily concerned with identification and range. Although most give some information on reproduction and basic captive care, reference to breeding and rearing turtles in captivity is lacking. Reichenbach-Klinke and Elkan (1965), Wallach (1969, 1970, 1971), Dobbs (1973), Frye (1973, 1976), Murphy (1975) and others gave information on diseases and treatments in reptiles including turtles, and Murphy (1973) summarized published accounts of ailments in captive chelonians with some reference to care in captivity. Many scattered references can be found in various journals, each concerned with one or more aspects of turtle care and reproduction. However, there has been no attempt to outline the parameters necessary for successful reproduction and raising freshwater aquatic turtles in captivity, other than some early references to reproduction for economic reasons (Hildebrand, 1929).

Recently, Tryon and Hulsey (1977) described care and reproduction of captive bog turtles, Clemmys muhlenbergi, at the Fort Worth Zoo. Although this paper was concerned with only one species, many of the techniques described have been successfully used, in part, for other species of aquatic and semi-aquatic chelonians in the zoo. The present paper is a summarization of the techniques of care and maintenance that in recent years has contributed to successful chelonian reproduction, and the raising of hatchlings.

I wish to thank the staff of the Department of Herpetology, Fort Worth Zoological Park, especially David B. Heckard, J.P. Jones, and John E. Simmons for their help and encouragement during the preparation of this paper. Joel D. Wood is solely responsible for the development and success of the gelatin diet described herein. Special thanks go to Terry G. Hulsey, who spent endless hours developing many of the techniques presently in use at the zoo.

Several literature references are available on observations made either wholly or in part on turtles maintained at the zoo (Mehrtens, 1966, 1967, 1973; Campbell, 1972), and most of the individual animals received in the mid to late 1960's are presently thriving. Acclimation to captivity varies considerably; however, it has only been in recent years that most of the successful reproduction has taken place. Peaker (1969) stated that merely because captive reptiles seem to be thriving does not mean they will reproduce. Anyone with experience in keeping captive reptiles knows this to be true, and it applies to all reptile groups. Copulation may be observed on a regular basis, but no eggs or young result from these matings. Certain modifications of lighting, diet, temperature, and general care have led to the egg-laying and subsequent hatching of ten taxa of turtles in the years 1973 through early 1977, most in consecutive years. These include Reeves turtle, Chinemys reevesi, Texas slider, Chrysemys concinna texana, red-eared slider, Chrysemys scripta elegans, bog turtle, Clemmys muhlenbergi ,three-striped box turtle, Cuora trifasciata, crowned hill turtle, Geoemyda trijuga coronata, Ceylon hill turtle, Kinosternon leucostoma, giant mud turtle, Staurotypus triporcatus, and the Stinkpot, Sternotherus odoratus. Much of the egg-laying occurs in winter and spring, and as of 1 August 1977, hatchlings from several species were produced.



Geoemyda trijuga thermalis (Ceylon Hill Turtle) hatches after 120 days incubation.

ADULT MAINTENANCE

Most of the adult turtles are housed in four major exhibits according to geographical range. Pools vary from 500 to approximately 7000 liters, and dry areas for basking, resting and nesting are provided. Rock facades, waterfalls, and the use of live plants varies with each exhibit to give a naturalistic and pleasing effect for the public and perhaps the animals therein. Several of these are mixed exhibits containing crocodilians. For example, in the African hall, the "Congo River" scene contains a 2000 liter pool and houses two male and two female West African dwarf crocodiles, Osteolaemus tetraspis and several turtles of the genera Pelomedusa and Pelusios. The South American hall contains the 7000 liter "Amazon River" exhibit housing three male and two female Yacare caiman, Caiman crocodilus yacare and turtles of the genera Chelydra, Chrysemys, Dermatemys, Kinosternon, Phrynops, Podocnemis and Staurotypus. The majority of reproduction in 1976 occurred in the 4000 liter Australia-Asia turtle exhibit which houses Chelodina, Chinemys, Clemmys, Cuora and Geoemyda. Although each exhibit varies according to pool size, available land area, and the number and size of species, each has certain similarities which I feel are responsible for successful reproduction.

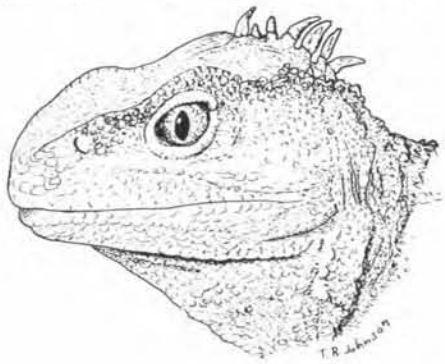
Artificial lighting is provided between 0800 h and 1730 h daily by Vita-lite fluorescent tubes (Durotest Co.), suntubes (Westinghouse FS 40, T 12), and spotlights of various sizes. Turtles exposed to insufficient ultra-violet radiation cannot synthesize certain essential vitamins (D2, D3) which help absorb calcium (Pritchard and Greenhood, 1968; Wallach, 1971; Moll and Legler, 1971). Deformed shells as well as other bony structures, and eggs with improperly formed shells may be signs of inadequate lighting. In 1972, each of our enclosures was supplied with one to eighteen 40 watt (four foot) Vita-lite fluorescent tubes, depending on exhibit size. Not only do these produce a natural "daylight" type lighting, but Vita-lite provides approximately ninety-one percent of the natural ultra-violet radiation (Laszlo, 1969). One or more 40 watt tubes are supplied for basic lighting at the front of each exhibit 1 m to 1.5 m from the basking areas. Additional double four-foot fluorescent fixtures are added as necessary 1.5 m to 2.5 m above the exhibit floor or pool surface. The importance of Vita-lite cannot be underestimated, and in addition to the animals, most indoor plants will thrive with its use in an exhibit.

In addition to Vita-lite, some exhibits utilize one or two 40 watt suntubes at a distance of 2 m to 2.5 m above the turtles. Although these can be used interchangeably with Vita-lite tubes in fluorescent fixtures, it is recommended that these be placed no closer than 1.5 m above the animals or possible ultra-violet overdose may result. If suntubes must be installed closer, the duration shall be approximately half of the 0800 h to 1730 h cycle. I have seen appetites in both turtles and lizards increase after exposure to suntubes 1-2 h daily. It also seems apparent that ultra-violet radiation destroys certain harmful bacteria and fungus. Any aquatic situation can be a haven for such, especially when animals and their food items are invovled, and if left unchecked, disease can quickly wipe out an entire turtle collection. Although chelonian disease is beyond the scope of this paper, I feel that the use of proper artificial lighting has helped to successfully prevent outbreaks of pathogenic problems in the zoo's collection. Finally, a reduction of certain unpleasant odors originating in the cage occurs after the installment of suntubes. I feel this to be a direct result of reduced bacterial growth.

One or more strategically placed 250 watt spotlights give turtles a chance to bask and thermoregulate in certain parts of the enclosure. Murphy (1969, 1972) described these conditions as "hot spots" creating thermal gradients. In general, the greatest amount of heat is usually in these areas, and an animal utilizing the "hot spots" has an opportunity to dry out and possibly metabolize more thoroughly. A less variable enclosure temperature can be established through the use of 25 watt floodlights. These are used only infrequently in smaller enclosures, however, for it is felt that a range of temperatures should be available at most times. In addition, flood lights tend to eliminate the darker areas which most reptiles, including the turtles, need and utilize to a greater or lesser degree as places of refuge.

Most enclosures receive a certain amount of natural sunlight through clear skylights above each herpetarium section. Daybreak and total darkness generally extend the 0800 h to 1730 h period of artificial lighting. I feel that seasonal fluctuations in photoperiod are important for proper reproductive cycling in most temperature and subtropical species. What degree of importance photoperiod plays and how it relates to temperature fluctuations, rainy vs. dry seasons, etc., has yet to be determined for the majority of reptiles. It most probably varies somewhat from species to species found in the same general locality. Fitch (1970) stated that some reptiles reproduce regularly at the same season of the year regardless of captive conditions. While this may be true for some, it is definitely not true for most species, and it is perhaps best to attempt to duplicate the natural environment of each animal or animal group as accurately as possible. For most, this would indicate daily and seasonal fluctuations in photoperiod and temperature.

Most reptile buildings historically have been by far the warmest of all zoo facilities. Whether this resulted from assumptions or misinformation is not clear, but it probably continued as a form of tradition. Few early references were available on thermal requirements of reptiles, and all too often it was thought that, for example, since a species was tropical, and all tropical regions are "hot", then that species must be constantly maintained in the warmest possible atmosphere. Little thought was given to conditions within the particular habitat. There is a considerable temperature variation from one life zone to another, whether it be tropics or elsewhere, and this must be taken into account not only for proper maintenance but for reproduction in captivity.



Most chelonians spend a certain percentage of their time basking in full sunlight. At such times, body temperatures may be optimum (preferred), and basking turtles will usually remain so until a voluntary maximum temperature is attained, at which time they will retreat into the cooler water or some shady area. Thermoregulation is apparently extremely important for all chelonians (Moll and Legler, 1971; Brattstrom and Collins, 1972), and there is evidence that they thermoregulate underwater at various depths and at low ambient temperatures (Brattstrom, 1965; Gibbons, 1967). Tortoises of several species have been observed periodically within a small rectangle of natural sunlight provided through skylights after they were moved indoors for the winter. Brattstrom (1965) recorded body temperatures of a number of turtles that ranged from 8 C to 37.8 C with a mean of 28.4 C, and concluded that thermal tolerance may differ accord-

ing to taxa. In addition, although reptiles with low thermal tolerances are active in colder areas, tropical forms did not have higher thermal preferences than temperate species. Tropical species, however, cannot tolerate conditions of cool or cold temperatures.

Though captive chelonians must be kept within certain temperature limits for successful maintenance, these limits may not necessarily be suitable for reproduction. Murphy (1973) suggested a daily range of 26.6 C to 32.2 C for most turtles, and that some reptiles can adjust to lower available temperatures. Licht (1965) and Licht and Basu (1967) concluded that spermatic destruction can occur if a constant optimum body temperature is maintained, and that photoperiod and temperature are closely related for certain reptiles. Herein lies the fallacy that continuous optimal heat must be supplied to captive reptiles. The Fort Worth Zoo has been successful in reproducing 52 total species and varieties of reptiles since 1971, and it is believed that lowered and fluctuating temperatures were a major factor.

Approximate temperature varies from 35 C in the areas of the "hot spots" to 22 C in shaded areas of the turtle exhibits in summer, and from 30 C to 20 C respectively in the winter. Quite naturally, basking is limited to shorter periods of time during the warmer months, and in the winter may continue throughout the eight hour period of artificial lighting. Tempered water at an average temperature of 25 C is used during weekly or semi-weekly exhibit cleaning. Each exhibit is provided with an overflow and a continuous supply of tempered water is available. Turtles reaching their preferred maximum body temperature while basking can utilize the water and will not be subjected to thermal shock due to cold winter water supply.

Cleanliness of chelonian facilities cannot be underestimated. Each exhibit is drained, thoroughly cleaned and refilled at least once each week, usually the day after the heaviest feeding. Most frequent water changing is undesirable because of the stress on individual turtles and because of the relative high chlorine content found in most metropolitan water supplies. Murphy (1973) stated that some hatchling turtles keep their eyes closed when subjected to fresh tap water. I have seen this to be true also for adult turtles, and certain aquatic salamanders (Amphiuma, Andrias) and anurans show a marked dislike for fresh tap water regardless of temperature. Frequent cleaning can be avoided by various types of filters which will keep water quality at a high level. Large (2000 to 7000 liter) exhibits are serviced by filters available for swimming pools. Smaller enclosures are serviced by diatomaceous earth, power, or airline filters of appropriate size. Ideally, a standard aquarium power filter is suitable for a 38 to 76 liter aquatic facility depending on the number of individuals, and filter size should be directly proportional to the increase in water volume. At no time however, should filtration preclude proper cleaning.

OFF-EXHIBIT FACILITIES

To a greater or lesser degree, most zoo reptile buildings contain off-exhibit facilities. Aside from obviously having more animals than exhibit space permits, certain factors necessitate housing animals in these enclosures. These may be for 1--newly received specimens which are isolated until they are considered free of contagious disease, 2--separation of individuals at certain times of the year for reproductive reasons, 3--animals developing signs of illness, and 4--certain shy individuals or species that are considered valuble to the collection yet do not acclimate to exhibit conditions.

Recently acquired specimens should be subjected to a period of strict quarantine. This may be several weeks to several months, depending upon the species and its history prior to accession. Murphy (1973) suggested soaking all incoming turtles in a broad spectrum antibiotic such as tetracycline hydrochloride (Polyotic). This can be mixed directly with tempered water in a ratio of one teaspoon to one liter of water, or until a light orange color is achieved in solution. The animal can then be placed in it, usually for a period of 24 hours. Once the specimen is established in a temporary enclosure, careful observation of feeding and general behavior is essential. One sure sign of health is the appearance of the feces. Most experienced persons can judge the health of their animals by a quick glance at fresh feces. Loose, mucoid, discolored, or bloody stools are usually signs of some problem (see Murphy, 1975). More than one collection has lost numerous specimens through the simple addition of one un-quarantined turtle to a mixed exhibit.

Certain shy species or those that cannot compete in a mixed exhibit are placed in off-exhibit enclosures. These include aquaria of various sizes, galvanized metal stock tanks, and specially constructed, waterproofed, wooden boxes. Although not on exhibit, these turtles are maintained under the same conditions of temperature and lighting available for exhibit enclosures. Tryon and Hulsey (1977) described off-exhibit housing for adult Clemmys muhlenbergi. This was apparently adequate for this species' well-being, and eggs and hatchlings were produced in two consecutive years. One advantage of these enclosures is that they can be easily moved outdoors during the warm months. Natural sunlight is far superior to any artificial lighting arrangement, and an even greater seasonal temperature fluctuation may be available. Possibly, any small to medium sized adult chelonians (100-200 mm carapace length) can be successfully maintained and reproduced in relatively simple enclosures if areas for basking, hiding, and nesting are provided.

A typical off-exhibit enclosure consists of a rectangular wooden box with average dimensions of 130 x 75 x 36 cm. Silicone aquarium sealer is used to prevent leakage, and then a neutral colored, non-toxic, waterproof paint is applied to the inner and outer surfaces. A waterproof plastic pan is placed in one corner of the box, encompassing approximately one-fourth of the total area. Rocks are placed around the pan at the water level to provide wet, dry, or intermediate areas of thermoregulation and easy access to the pan. The pan is filled with 2.5 cm of pea gravel for drainage and covered with 5.0 to 10.0 cm damp sphagnum moss. This provides an area for seclusion and nesting.

Indoors, each enclosure is provided with one or two 40 watt Vitaline tubes from 2-4 m distant that are on from 0800 h to 1730 h daily. In addition, a 250 watt spotlight is suspended 1 m above the sphagnum filled pan to provide a thermal gradient. Temperatures directly under the spotlight during the cool months average 30 C at midday. Temperatures under the layer of sphagnum average 23 C, and water temperature averages 23 C.

In April or May of each year these facilities are moved outdoors and placed in an area where partial shade is available during the warmest hours of the day. Each is covered with a secure lid of 38 mm mesh to prevent predation from cats, raccoons, and zoo visitors that may

wander into the area, yet provides for the passage of full sunlight. During the warmest months, a board is placed longitudinally which covers half of the enclosure, providing areas of both sunlight and shade. Logs, corkbark or boards are added occasionally to provide additional basking areas, depending on the number of turtles housed. In mid-September or early October, or when the temperature begins to attain lows of 8 C to 10 C for temperature species and 16 C to 18 C for tropical forms, the enclosures are moved indoors. Care must be taken to assure that water temperature remains somewhat below 30 C on the warmest days.

Experience seems to be the only test for variations of compatibility. Certain species require housing on a one to one sex ratio and isolation from other forms, while others will thrive in mixed situations (such as exhibits) housing not only others of the same sex and species but other genera. In my experience, Clemmys muhlenbergi should be maintained in a ratio of one male to one to several females. Although males may be switched from one enclosure to another, placing two males together may result in continuous fighting, often resulting in intimidation, injury, or death. If separated, all male specimens may be reproductively active, but if not, the subdominant individuals may never have a chance to breed and their health may suffer. Conversely, Clemmys guttata may successfully be maintained in situations housing more than one male. Other examples include Graptemys versa, where females will periodically attack the smaller, sexually dimorphic males during non-reproductive seasons, and two Fly River turtles, Carretochelys insculpta, although totally compatible with other species, that would fight savagely whenever placed together. Intraspecific and interspecific differences vary considerably and must be judged accordingly.

DIET AND FEEDING

Adequate nutrition plays a major role in successful chelonian reproduction. Most major works on turtles (Pritchard, 1967; Ernst and Barbour, 1972, and others) that include aspects of captive care treat feeding lightly. It can be generally concuded, however, that there are two major types that can be grouped according to feeding strategies. These are the tortoises, that are mainly herbivorous, and the aquatic forms, which are largely carnivorous, or omnivorous to a degree. Inadequate nutrition can not only prevent reproductive cycling, but can lead to a multitude of physical problems (Murphy, 1973; Frye, 1976). Edgren (1960) stated that calcium loss and a decrease in bone density occurs in female Sternotherus odoratus at the time of egg-laying, and this must be compensated for through proper nutrition. Conversely, a properly fed turtle may not develop disease even if exposed. It is no wonder that turtles maintained on the dried insect diets sold in pet stores, or on hamburger meat and lettuce, inevitably develop nutritional deficiencies and other maladies.

Composition of Foods (Watt and Merrill, 1963) gives insight into the variety of nutrients contained in food items. A continuous diet restricted to one or two food items is inadequate. For example, two common foods used by many private turtle fanciers are raw hamburger meat and lettuce. Raw hamburger (regular ground), while containing 268 calories per 100 g portion, provides only 17.9 g protein, 21.2 g fat and no carbohydrates. In addition, important vitamins are present only in traces if at all (40 I.U. Vit. A, .08 mg Thiamine, .16 mg Riboflavin, 0.0 mg Vit. C). Raw lettuce of any type is even worse. It is approximately 95 percent water, and 100 g provides 13 to 18 calories, 0.7 to 1.3 g protein, and the same traces of vitamins as does the hamburger with the exception of vitamin A (330 to 1,900 I.U.) and vitamin C (6 to 18 mg).

The exact daily nutritional requirements for aquatic turtles have not been determined, but the key consideration for any turtle diet is a broad variety of different food types (see Folkerts, 1968; Punzo, 1974). Adult chelonians at the zoo are fed two or three times per week, and food items vary with each feeding. Most aquatic and semi-aquatic turtles prefer to ingest their meals underwater. They will, however, feed on land where water is unavailable, or when competititon is too great under the surface. Some will frequently grasp the largest available piece of food and rapidly carry it up onto the land area where it can be slowly consumed. Any combination of spaced feeding days is acceptable, but adherence to a schedule is most important. Periodic fasting will not hurt turtles in good condition, and they may voluntarily fast during the coolest and warmest months. Hutton (1960) indicated that metabolism may be internally controlled and independent of all but gross changes in temperature. If appetites diminish, it is always best to feed the food items of highest nutritional value. When appetites are at their peak, so should be the variety of food items offered. The first day of the three day schedule includes a salad type mixture of diced apples, oranges, carrots, onions, lettuce, bananas, Bird of Prey Diet (ZuPreem Co.), Marmoset Diet (ZuPreem Co.), and mealworms. Combinations vary seasonally, and periodically tomatoes, squash and even hard boiled eggs are offered. The salad can be placed in the water, but it is better to leave the tray at the pool's edge thereby assuring that separation of the different items will not occur. Two days later, feeding may utilize some whole animal or animal parts, such as skinned mice. Using the entire animal permits ingestion of internal organs, and these contain the majority of essential nutrients. The mice are skinned to prevent ingestion of a large bulk of non-nutritive hair and skin, to prevent amounts of the undigested hair in feces that may foul the water and clog the filters, and simply to make feeding easier for the turtles. If animal parts are used, it is preferable to feed both entrails and muscle tissue. Turtles will relish hairless, newborn mice, and these are used periodically; however, they lack complete development of certain internal structures, such as the skeletal system, and this may result in a deficiency if fed too frequently. Feeding on the third day consists of a specially made supplemental food called "turtle gelatin". This method was first described as a diet for aquarium fish (Peterson, et al., 1968), but was later used in various forms as food for chelonians at the Philadelphia Zoo (Conant, 1971) and the Fort Worth Zoo. This highly successful food was developed through much trial and error, and has proven to be the best method of supplying turtles with the greatest possible degree of nutritive value and variation in the least amount of food ingested. Since it is highly concentrated, feeding should be restricted to once per week for most turtles. It can be fed more frequently to sickly or starved individuals. Turtle gelatin is made as follows:

1) Line a large chafing dish with 40 g Bird of Prey Diet and 200 g Marmoset Diet (ZuPreem). Over this sprinkle a mixture of:
   - 1/2 cup ground shrimp meal
   - 1/4 cup ground bone meal
   - 3 200 I.U. caps of vitamin E
2) In an electric blender, mix:
   - 1 cup gelatin (Knox unflavored)
   - 2 cups steaming hot water
   - 1/2 cup fresh, thawed spinach
   - 1 1/2 cups chopped carrots
   - 1 jar baby food spinach
   - 1/4 cup mealworms
3) When thoroughly mixed, pour this over the contents in the chafing dish.

The entire dish should then be placed in a freezer until gelled but not frozen. At this time it can be cut into cubes of various sizes. One cube 2.5 cm to 5.0 cm is adequate for any small to medium sized turtle. Since the cubes are gelled,

they can be thrown directly into the pools and will dissolve very slowly, thereby assuring that most will be consumed. Unused gelatin cubes can be stored for up to a week at normal refrigeration temperatures or frozen for extended periods. Obviously, any combination of fruits, vegetables, baby foods and insects can be used. Chopped liver, raw beef, or skinned, chopped mice can be substituted for the prepared ZuPreem products. It is important, however, that the ground meals and vitamins be used with each preparation. It must be remembered that this is a supplement and should be used in conjunction with a varied diet containing other meats, vegetables, and insects. When this supplement was first used, several turtles that had not increased in size appreciably in years showed new growth.

FATAL TOAD POISONING IN SNAKES

The toxic nature of the secretion from the paratoid and other dermal glands of toads (genus Bufo) is well known. Jensen and Westphal (1956) note that it contains cardiotonic and hypertensive elements and is highly toxic to cats and dogs.

Many species of snakes display a tolerance to toad venom and include these amphibians in their diets. Conversely, other snake species, including some frog-eaters, shun toads as food. Licht and Low (1968) found that toad-eating Thamnophis sirtalis tolerated force-fed dosages of toad venom that killed similarly dosed individuals of several species of Masticophis and Salvadora, snakes that do not eat toads.

Tschambers (1948) reports the case of a snake, Dinodon semicarinatum, feeding regularly on frogs but dying shortly after ingesting a toad, Bufo americanus. The following two similar incidents occurred more recently at the Baltimore Zoo.

Ten Madagascan tree boas, Sanzinia madagascariensis, born on 18 August 1971, all fed mainly on newborn mice and hamsters but one also would accept small frogs and salamanders of various species. The latter snake devoured a small toad, Bufo woodhousei fowleri, on 30 January 1972 and thereafter was unobserved until found dead the next morning.

Ten Madagascan hognosed snakes, Lioheterodon madagascariensis, that hatched on 24 June 1976 fed on several types of frogs and salamanders. One snake was offered a small Bufo w. fowleri on 8 July 1976. This snake held the toad in its mouth for about five seconds, released it, then began to writhe violently and died within five minutes. Post mortems performed on our two snakes showed no signs of disease or other significant pathology

but did not exclude the possibility of toad poisoning.

It is noteworthy that all three of the above snakes were from toad-free areas. Sanzinia and Liopheterodon are endemic to Madagascar, where toads have never occurred (Savage, 1973). The Dinodon was from an unknown locality in the Ryukyu Islands, where one toad, Bufo bufo gargarizans, occurs only on Miyako and may have been introduced there recently (Inger, 1947). Although Dinodon semicarinatum is recorded from several of the Ryukyus, it is not known, as far as we can discover, from Miyako.

Susceptibility to toad venom well may be the ancestral state of snakes in general. Some species may have added toads to their diets as a result of competition for food and, probably through natural selection, became resistant to the venom. Obviously, snakes occurring in toad-free regions would not develop such resistance.

Legislative Alert

Legislation and Rulemaking Re: Herps

In accordance with the idea of keeping our constituency informed of U.S. Federal legislative activities involving reptiles and amphibians, the following is a brief review of the 1977 wildlife regulations affecting "herps":

In May, 1977 published regulations (F.R. Vol. 42, No. 35 - Tuesday, February 22, 1977) became effective relative to enforcement of the Convention on International Trade in Endangered Species of Wild Fauna and Flora. The U.S. and nearly 40 other nations are party to the Convention which has established procedures to control and monitor the import and export of species covered by the treaty.

The Convention and Endangered Species Act (87 Stat. 884, 16 U.s.C. 1531-43) of 1973 share many similarities in that the protection they provide extends to species worldwide; however, it is important to point out that these separate measures - one domestic and the other international - employ different terminology, address separate (but overlapping in some instances) lists of protected species, and, in addition, serve somewhat different purposes.

The primary function of the Convention is to regulate international trade in the species it protects. Its rules apply only to import, export, and re-export. The rules do not apply, as part of the international document, to interstate shipments, to the "taking" (killing or capture) of species, or to the preservation of habitat. The Convention approaches the protection of species from the standpoint of how trace (import-export) would affect the status of a particular species in the wild in its native country. The scope of the Convention extends to animals and plants, terrestrial or aquatic. Accordingly, the Convention recognizes that controls are essential now for many imperiled species, and that safeguards are necessary for others that could be jeopardized by a high demand in import-export markets (e.g., reptile skins). The Convention established three appendices, or categories, of species in order to provide for appropriate and differing degrees of control:

--Appendix I: Species that are threatened with extinction and are or may be affected by trade. These species are in need of particularly strict regulation to prevent their future endangerment.

--Appendix II: species that, although not now necessarily threatened with extinction, may become so unless their trade is regulated and monitored.

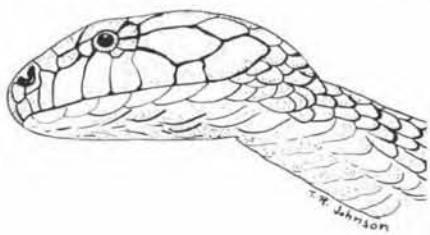
--Appendix III: Species may be placed on this Appendix by any individual Convention nation (i.e., a nation party to the treaty) as being subject to conservation regulation within its jurisdiction, to gain the cooperation of other countries in re-inforcing its conservation measures. Any nation may list a species native to its country on this Appendix without approval of the other parties to the Convention.

The U.S. Endangered Species Act is broader than the Convention in its application and applies to all jeopardized species that warrant Federal protection - including those endangered by habitat destruction and many other things, whether or not they are of value in the commercial market. The act regulates the taking and capture of all listed animals (and plants), as well as interstate and foreign commerce in both animals and plants, and provides for land acquisition and financial assistance to States and foreign countries. The act provides protection to any species threatened by any of the following factors: 1) the present or threatened destruction, modification, or curtailment of the species' habitat or range; 2) overutilization for commercial, sporting, scientific, or educational purposes; 3) disease or predation; 4) the inadequacy of existing regulatory mechanisms; and 5) other natural or man-made factors affecting the species' continued existence. Two living classifications are provided:

--Endangered: Any species that is in danger of extinction through all or a significant portion of its range.

--Threatened: Any species that is likely to become "Endangered" within the foreseeable future through all or a significant portion of its range.

NOTE: Other U.S., State, local, and foreign laws may also apply to species listed under the Act and/or Convention. It is the responsibility of the individual to learn about and comply with all applicable laws. More specific information on the provisions of these laws, as well as permit applications and list of protected species, may be obtained from the Federal Wildlife Permit Office, U.S. Fish and Wildlife Service, Washington, D.C. 20240 (phone: 202/634-1496).



Other legislative notes: In February, 1977 the U.S. Fish and Wildlife Service reclassified the status of the American alligator (Alligator mississipiensis): populations throughout Florida and in coastal areas of South Carolina, Georgia,

Louisiana, and Texas have been reclassified from Endangered to Threatened; populations inhabiting Alabama, Mississippi, North Carolina, Oklahoma, and inland portions of South Carolina, Georgia, Louisiana, and Texas are still classified as Endangered.

In October, 1977 it was announced that the Fish and Wildlife Service and the National Marine Fisheries Service have agreed by memorandum of understanding to divide program responsibilities covering sea turtles listed under the Endangered Species Act of 1973. Henceforth, NMFS will have sole jurisdiction over sea turtles (including parts or products) when they are in a marine environment (in the oceans, seas, bays, estuaries, brackish water areas, and waters adjacent to nesting beaches). FWS will have sole jurisdiction when the turtles (including parts and products) are on land. The Federal Wildlife Permit Office of the FWS will serve as the central clearinghouse for both agencies in the processing of permit applications and certifications affecting sea turtles.

Final note: Many of our colleagues have complained of not receiving adequate notice of Federal legislative actions involving reptiles and amphibians. The SSAR Board SSAR Conservation Committee are currently working to alleviate this problem by establishing a network of communication among the national and regional herp societies that will allow rapid (within 48 hours of receipt in the Herp Review office) dissemination of legislative information. This system should be fully operational in early Spring, '78.

THOMAS J. BERGER, Museum of Natural History, The University of Kansas, Lawrence, Kansas 66045.

New Endangered/Threatened Species

Persons working with Hyla andersonii (Florida populations only) and Eleutherodactylus jasperi are advised that these have been respectively designated Endangered and Threatened. Also, critical habitat for both species has been described. See Federal Register Volume 452, Number 218 (11 November 1977) for details.

Geographic Distribution

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same. The standard format for a geographic distribution record is:

Scientific name (common name) as it appears in Conant (1975) or Stebbins (1966). Locality (use metric for distances). Date and collector(s). Identified or verified by. Place of deposition and catalogue number. Comments. Citation. Submitted by (give name and address).

Please submit new geographic distribution records in the standard format only to Joseph C. Mitchell, Graduate Program in Ecology, University of Tennessee, Knoxville, Tennessee 37916. Short manuscripts are acceptable when data cannot be adequately presented in the standard format.

Recommended citation for new geographic distribution records appearing in Herpetological Review is: Jones, J. 1977. Geographic distribution: Rana pipiens. SSAR Herp. Review 8(1): 1.

Caudata

AMBYSTOMA TALPOIDEUM (Mole Salamander). USA. ARKANSAS: Columbia Co. 11.2 km E Magnolia on Co. Rd. 61. 17 April 1977. S. Winters. Two specimens verified by H.W. Robison and M.A. Nickerson. S. Arkansas Univ. Vert. Coll. uncataloged and Milwaukee Pub. Mus. (MPM 15281). Third record for Arkansas and extends the known range ca. 410 km SW of nearest known localities in Clay County (FMNH 2903) (Parker, 1947, Proc. Ark. Acad. Sci. 2:17) and 367 km from a locality in Crittenden Co. (C.R. Shoop, pers. comm.), northeastern Arkansas.

Submitted by HENRY W. ROBISON and STEPHEN WINTERS, Division of Biological Sciences, Southern Arkansas University, Magnolia, Arkansas 71753.

HEMIDACTYLIUM SCUTATUM (Fourtoed Salamander). USA. MAINE: Hancock Co: Salisbury Cove. 30 April 1958. C.R. Terman. Verified by S.L. Davis. Collection of C.R. Terman. First specimen for county and second for state. First state record from Kennebec Co. (Fowler, 1942, Copei 1942(3): 185-186). 1 km E Bucksport. 8 May 1976. S.L. Davis. Released after identification. Penobscot Co: 1.5 km W Old Town. 29 April 1976. B.N. Burgason. Verified by Richard G. Zweifel. Amer. Mus. Nat. Hist., AMNH 92881. These records confirm this salamander's presence in Eastcentral Maine (Neill, 1963. Cat. Amer. Amph. Ret., 2.1).

Submitted by BARRY N. BURGASON, School of Forest Resources, University of Maine, Orono, Maine 04473 and SHIRLEY L. DAVIS, Gardiner Road, Orono, Maine 04473.

PSEUDOEURYCEA SCANDANS. MEXICO. San Luis Potosi: 27.7 km NE Ciudad del Maiz. 18 July 1976. E.A. Liner, R.M. Johnson and A.H. Chaney. EAL 4216 (2 sp.). First record for the state and extends range of this species approx. 64.4 km airline SW of the previously known range in Tamaulipas (Walker, 1955, Occ. Papers UMMZ, 567: 1-8; Smith and Smith, 1976, Synopsis of the Herpetofauna of Mexico. IV. Source Analysis and Index for Mexican Amphibians, J. Johnson).

Submitted by RICHARD M. JOHNSON, 4170 Lantern Lane, Mobile, Alabama 36609, ERNEST A. LINER, 310 Malibou Blvd., Houma, Louisiana 70360 and ALLEN H. CHANEY, Box 2092, Texas A&I University, Kingsville, Texas 78363.

Salientia

PELOBATES SYRIACUS SYRIACUS (Southwest Asian Spadefoot). IRAN. MAZANDERAN PROVINCE: 14 km W Babol Sar, public beach on Caspian Sea, ca 36 41'N, 52 29'E. 28 May 1975. S.C. Anderson. Iran Nat. Mus. Nat. Hist. (Muze'-ye Melli-ye Tarikh-e Tabi'i), Tehran, MMTT 1130. Easternmost record for species, first record for Mazanderan Province. Extends range eastward along Caspian Coast ca 285 airline km from Bandar-e Pahlavi (37 28'N, 49 27'E), Gilan Province. (Tuck, 1971, Bull. Maryland Herp. Soc., 7: 51. Eiselt and Schmidtler, 1973, Ann. Naturhistor. Mus. Wien, 77: 182-184).

Submitted by STEVEN C. ANDERSON, Raymond/Callison College, University of the Pacific, Stockton, California 95211.

PSEUDACRIS STRECKERI STRECKERI (Strecker's Chorus Frog). USA. KANSAS: Harper Co: 2.0 km W, 0.9 km S Anthony. 30 April 1977. E. Stegal, E.R. Byrne, D. Grow, and P. Gray. Univ. Kansas Mus. Nat. Hist, KU 174370-174371. First record for the state and extends range northward into Kansas. Verifies Collins' prediction and possible natural occurrence in Kansas (Collins, 1974, Amphibians and Reptiles in Kansas, Univ. Kansas Publ., Mus. Nat. Hist.). Calling in association

with Bufo woodhousei woodhousei, Acris crepitans blanchardi, and Rana pipiens.

Submitted by PETER GRAY, Sedgwick Co. Zoological Society, 5555 Zoo Blvd., Wichita, Kansas 67212. ●

RANA MACROCNEMIS PSEUDODALMATINA (Iranian Long-legged Wood Frog). IRAN. MAZANDERAN PROVINCE: Mohamad Reza Shah National Park, 9 km E Park HQ, ca 37 21'N, 56 12'E. 800 m elev. 30 May 1975. S.C. Anderson and R. McCullers. California Acad. Sci., CAS 141169. Easternmost record for species. Extends distribution ca 450 airline km northeastward of Weyser (type locality) to the eastern limits of the Hyrcanian Forest zone in the Kopet Dagh. (Eiselt and Schmidtler, 1973, Ann Naturhistor. Mus. Wien, 77: 215-20. Tuck, 1974, Herp. Rev., 5: 107).

Submitted by STEVEN C. ANDERSON, Raymond/Callison College, University of the Pacific, Stockton, California 95211. ●

TESTUDINES

CHRYSEMYS CONCINNA HEIROGLYPHICA (Slider). USA. TENNESSEE: Marion Co: 2.0 km SSE Haletown, E. Shore Nickajack Lake (Tennessee River). 26 June 1976. J.B. Iverson. Florida St. Mus., Univ. Florida, FSM/UF 36993. Extension of range 93 km NE in the Tennessee River (Mount, 1975, The Reptiles and Amphibians of Alabama, Auburn Univ. Agric. Exp. Station).

Submitted by JOHN B. IVERSON, Florida State Museum, University of Florida, Gainesville, Florida 32611. ●

SAURIA

COLEONYX VARIEGATUS PENINSULARIS (Banded Gecko). MEXICO. BAJA CALIFORNIA SUR: Isla Espiritu Santo. 12 May 1977. R.L. Seib. California Acad. Sci. 143259. A single adult male specimen found active at night at Playa La Bonanza on south end of island. Only previous island record Isla San Jose. Other subspecies on Islas San Marcos, Santa Inez, and Tiburon (Soule and Sloan, 1966, Trans. San Diego Soc. Nat. Hist., 14: 137-156).

Submitted by ROBERT L. SEIB, Department of Geography, University of California, Berkeley, California 94720. ●

EREMIAS ACUTIROSTRIS (Reticulate Desert Fringe-footed Lizard). IRAN. SISTAN PROVINCE: 10 km Sw Rud-e Hirmand, abandoned village SE of road from Zabol to Dust-e Mohammad Khan, ca 31 03'N, 61 38'E, 45 m elev. 28 April 1975. R.G. Tuck, Jr. and S.C. Anderson. Iran Nat. Mus. Nat. Hist. (Muze'-ye Melli-ye Yarikh-e Tabi'i), Tehran, MMTT 937, 940-941, California Acad. Sci, CAS 141099. First record for Iran. Extends distribution ca 240 km westward of westernmost Afghanistan record and ca 360 km northwestward of westernmost Pakistan record (Leviton and Anderson, 1970, Proc. California Acad. Sci., ser. 4, 38: 187. Mertens, 1969, Stuttgarter Beitr. Naturk., 197: 43).

Submitted by STEVEN V. ANDERSON, Raymond/Callison College, University of the Pacific, Stockton, California 95211. ●

SCELOPORUS GRACIOSUS GRACIOSUS (Sagebrush lizard). USA. NORTH DAKOTA: Slope Co: 19.7 km NNE Marmarth, 46.0 km W Amidon. 21 May 1977. G.H. Duckwitz and A.D. Heimerdinger. Verified by D.M. Hoppe. Univ. of Minnesota, Morris herptile collection, UMM 77-007. New county record and extends the published range 141 km S from McKenzie Co, ND (Conant, 1975, A Field Guide to Reptiles and Amphibians of Eastern and Central North America, Houghton Mifflin Co.; Wheeler and Wheeler, 1966, The Amphibians and Reptiles of North Dakota, Univ. North Dakota Press). Captured in a disjunct stand of limber pine, Pinus flexilis.

Submitted by DAVID M. HOOPE, Biology Department, University of Minnesota, Morris, Minnesota 56267. ●

SERPENTES

CROTALUS MITCHELLI PYRRHUS (Southwestern Speckled Rattlesnake). MEXICO. BAJA CALIFORNIA NORTE: Isla Piojo. 6 January 1977. R.L. Seib. California Acad. Sci., No. 143168. First record from this island situated in Bahia de los Angeles in the northwestern Gulf of California. Known from Isla Smith, 4 km NWN of Isla Piojo and the adjacent Baja Peninsula. C. mitchelli angelensis is endemic to Isla Angel de la Guarda. First specimen reported from Isla Piojo (Soule and Sloan, 1966, Trans. San Diego Soc. Nat. Hist. 14: 137-157). Numerous nests and dead young seabirds scattered about the island suggest a possible seasonal food source which could enable this tiny island to support a Crotalus population.

Submitted by ROBERT L. SEIB, Department of Geography, University of California, Berkeley, California 94720. ●

CROTALUS VIRIDIS CERBERUS (Arizona Black Rattlesnake). USA. NEW MEXICO. Grant Co: 37.0 km E. and 12.5 km. S. Glenwood. 19 August 1974. K. Mello. Verified by G.A. McVicker, B.L. Mello and J. Duval, NMSU. Private collection of G.A. McVicker. Extends range 78.9 km. SE of nearest recorded locality (pers. comm., W.G. Degenhardt).

Submitted by KIM MELLO, Department of Fishery and Wildlife Sciences, New Mexico State University, Las Cruces, New Mexico 88003. ●

ERYX JAYAKARI (Arabian Sand Boa). IRAN. KHUZESTAN PROVINCE: S of Shush. 18 November 1968. D. Lay and J. Hassinger. Field Mus. Nat. Hist., Chicago, FMNH 171251. 1 km E of Kupal, dunes near Ahvaz-Behbehan road, ca 31 16'N, 49 10'E, 25-50 m elev. 16 April 1975. R. Khazaie and S. C. Anderson. Iran Nat. Mus. of Nat. Hist. (Muze'-ye Turikh-e Tabi'i), Tehran, MMTT 1032. First records for Iran. Extends the range from the Arabian peninsula into the contiguous lowland areas of southwestern Iran. (Anderson, 1963, Proc. California Acad. Sci., ser. 4(31): 477. Leviton and Anderson, 1967, Proc. California Acad. Sci., ser. 4(35): 181-182).

Submitted by STEVEN C. ANDERSON, Raymond/Callison College, University of the Pacific, Stockton, California 95211. ●

OPHEODRYS VERNALIS BLANCHARDI (Western smooth green snake). USA. NORTH DAKOTA: Slope Co: 23.0 km N Marmarch, 44.3 km W Amidon. 21 May 1977. G.H. Duckwitz and A.D. Heimerdinger. Verified by D.M. Hoope, Univ. of Minnesota, Morris herptile collection, UMM 77-006. New county record and extends the published range 135 km SW from Dunn Co, ND (Conant, 1975, A Field Guide to Reptiles and Amphibians of Eastern and Central North America, Houghton Mifflin Co.; Wheeler and Wheeler, 1966, The Amphibians and Reptiles of North Dakota, North Dakota Press).

Submitted by DAVID M. HOPPE, Biology Department, University of Minnesota, Morris, Minnesota 56267. ●

TANTILLA NIGRICEPS FUMICEPS (Texas Black-Headed Snake). MEXICO. NUEVO LEON: 9.5 km SSW Cerralvo at Rancho El 86. 13 July 1976. E.A. Liner, R.M. Johnson and A.H. Chaney. EAL 4147. First record for the state and the third for Mexico; the first two recorded from Tamaulipas (Mier and 16.3 km SW Reynosa on Mexico 40), approx. 64.4 and 128.8 airline kms NW and E of this locality (Smith and Smith, 1976, Synopsis of the Herpetofauna of Mexico. Regional Society News

Second Regional Herp Society Conference at Tempe

The second Regional Herpetological Societies Conference, co-sponsored by the Arizona Herpetological Association and the SSAR will be held on 1 June 1978 at Arizona State University in Tempe. Conference co-moderators will be Jeffrey H. Black (Oklahoma Herpetological Society) and Tom R. Johnson (SSAR Board of Directors). Facilities will be made available to all state and metropolitan herpetological societies to display and sell their publications, solicit new memberships, communicate their goals, and meet with their colleagues from other regional herpetological societies. A program on topics of major interest to regional societies is planned and will be mailed to all individuals registering for the conference. Any societies interested in participating should contact the conference coordinator, as follows: Joseph T. Collins, Museum of Natural History, Univ. of Kansas, Lawrence, Kansas 66045, 913/864-4920 (Museum), 913/887-6549 (Residence).

The first RHSC, held last August in Lawrence, was a tremendous success. Over 70 representatives from 20 regional societies attended and participated. The SSAR strongly urges all regional societies to send representatives to Tempe on 1 June 1978. The SSAR needs your input to and support for future SSAR programs involving your organization.

Cincinnati Herp Society Formed

The Greater Cincinnati Herpetological Society (GCHS) was formed in 1977 as a vehicle for metropolitan Cincinnati herpetologists to exchange views and ideas about amphibians and reptiles, and to promote the welfare of these animals through education and responsible research. Membership is open to anyone with an interest in herpetology. Officers of the GCHS include the President, Vice-President, Secretary and Treasurer. The GCHS meets on the first Wednesday of each month at 7:30 p.m. at the Cincinnati Museum of Natural History, with the annual meeting set for October of each year. The GCHS issues a Newsletter which is sent to all members. Persons wishing to join the GCHS should consult the following Society dues schedule: Individual dues--$5.00; Family--$10.00; Student--$3.00; Corresponding--$3.00; and Institutional--$15.00. Dues should be sent to: Bill Maynard, GCHS Secretary, 2992 West McMicken Avenue, Apartment #3, Cincinnati, Ohio 45225.

News Notes

Letters to the Editor

22 September 1977
Reference: JNO/16/9/16/8

I have read with great interest the correspondence generated by Dr. James Lazell's letter condemning alligator translocation in the September 1976 issue of Herp. Review. I must say at the outset that my reaction to Lazell's letter was one of pure delight, and like C.A. Ross, I was disappointed by Bowler's reply.

What Lazell is advocating is that we adopt the principles of "genetic conservation", a refined form of "nature conservation". Genetic conservationists are rare birds, but are increasing in number very satisfactorily, despite a sad lack of published statement explaining what is meant by genetic conservation. At a recent symposium on African Wildlife research in Pretoria South Africa (July 1977) I defined it as the management of living things in such a way as to prevent unnecessary loss of genetic variation, to protect species from introgression and unnatural hybridization, and to conserve the genetic integrity of subspecies and ecotypes by discouraging ill-considered translocations, this, in the full recognition that the long-term conservation of life depends upon the maintenance of the rich store of genetic variation bequeathed to us by aeons of evolution.

The Audubon Society's alligator exercise, to my mind, offends against the principles of genetic conservation. We cannot gaily embark upon translocation lacking genetic knowledge, yet how much is known about the extent of genetic ecotypic variation in plant and animal species? Precious little. This is something the genetic conservationist is not afraid to admit. But to those who equate "translocation" with "conservation", genetic differences between populations are only recognized if they give rise to easily detectable external morphological differences. Subtle physiological adaptations or cryptic local variations generally pass unnoticed.

In the present state of our genetic knowledge, a cautious approach to translocation is stock from the nearest available geographic resource, or ecotypic equivalent. This would apply both to an area from which a species has been extirpated, and to an area where it is felt necessary to supplement a precariously surviving population. Subspecies, or even ecotype, mingling may be successful in the short-term but no one can predict the long-term effects. There are several recorded instances of animal populations being weakened by the addition of ill-adapted genetic material from a different environment.

When the natural increase of a protected species eventually brings it beyond the carrying capacity of its available habitat, sentimental taboos are often invoked to rule out the two sensible solutions--destruction or utilization--in favour of translocation. But it should be noted that we have an evolutionary responsibility to prevent genetic panmixia, whether a deleterious effect is anticipated or not.

Lastly, I disagree with Bowler and Blakeney on the definition of the term "exotic". The genetic conservationist's definition is that an exotic is a species, subspecies or ecotype which is native to an area located outside the area under review.

J. C. GREIG (Herpetologist), P.P. Officer-In-Charge (Research), Jonkershoe Nature Conservation Station, Private Bag 504, Stellenbosch 7600, Republic of South Africa.

---

15 October 1977

In the December 1976 issue of Herpetological Review (just now received!) Donald Hahn attributes the first record of vertebrates in the diet of wild-caught Bufo to Campbell and Davis (1968) who asserted, "Vertebrates have not been reported in stomachs of field collected toads (genus Bufo)". This is untrue. Marx and Inger (1961) reported frogs and a skink in the stomachs of wild-caught Bufo regularis and a frog in the stomach of Bufo funereus, and it is not unlikely that earlier records may be found in literature unavailable to me here.

On the subject of Bufo eating snakes--about which Donald Hahn wrote his letter, I can add another record: One the night of 9th July, 1977 I found a female Bufo regularis in the act of swallowing, tail-first, a Leptotyphlops bicolor in a cement road-side gutter on the University of Ghana campus at Legon.

Vertebrates, usually anurans, don't seem too uncommon in the diet of other anurans; e.g., Marx and Inger (op. cit.) found vertebrates in the stomachs 12 of the 20 species of Zaire anurans with which they dealt. It is true that the incidence of vertebrates is usually low, but Marx and Inger found anurans in 21 of 106 (19.8%) stomachs of Ptychadena grandisonae, and Knoepffler (1976) has found cyprinodont fish in 62% of 169 food-filled stomachs of Aubria subsigillata. So perhaps one should not be surprised to find

vertebrates, even reptiles, forming a small but regular component in the diet of Bufo species.

SSAR ADDRESS CHANGES

SSAR members should note the new addresses for two society officers, as follows:

J.P. Kennedy
Department of Anatomy
Texas Medical Center
University of Texas
Houston, Texas 77030

Harry W. Greene
Laboratories of Anatomy
School of Veterinary Medicine
University of Pennsylvania
Philadelphia, Pennsylvania 19104

SYMPOSIUM ON THREATENED/ENDANGERED PLANTS AND ANIMALS TO BE HELD IN VIRGINIA

A symposium on the Endangered and Threatened Plants and Animals of Virginia is to be held May 19- 20, 1978 at Virginia Polytechnic Institute. For additional information please contact:

Donald Linzey
Center for Environmental Studies
Virginia Polytechnic Institute
and State University
Blacksburg, Virginia 24061

MASSASAUGA DISTRIBUTION DATA NEEDED

Data on the distribution of the Eastern Massasauga (Sistrurus catenatus catenatus) in Pennsylvania is needed to complete a detailed map. Desired are the localities where species were collected, released, or observed within the boundaries of Pennsylvania. This information will be used to compile a detailed map on the distribution of (Sistrurus catenatus catenatus) in the state of Pennsylvania, in which the status of this species can be determined. Please write: Mark A. Stahle, 1000 4th Street, New Cumberland, PA 17070.

THE JAPAN SNAKE INSTITUTE JOURNAL

The Snake, journal of The Japan Snake Institute, publishes general papers on all aspects of the biology of snakes, including medical papers on snake venom and snakebites. Complete sets of the journal are available, at the following prices:

Vol. 1, no. 1, 1969	$2.00
Vol. 2, nos. 1-2, 1970	4.00
Vol. 3, nos. 1-2, 1971	4.00
Vol. 4, nos. 1-2, 1972	4.00
Vol. 5, nos. 1-2, 1973	4.00
Vol. 6, nos. 1-2, 1974	6.00
Vol. 7, nos. 1-2, 1975	6.00
Vol. 8, nos. 1-2, 1976	6.00
Vol. 9, no. 1, 1977	3.00

Individuals or institutions desiring to subscribe should write to: The Japan Snake Institute, Yabuzuka-honmachi, Nitta-gun, Gunma Prefecture 379-23, Japan.

UIMNH HERPETOLOGICAL COLLECTION

After 1 January 1978, Dorothy M. Smith will no longer be associated with the herpetological collection at the University of Illinois Museum of Natural History. Inquiries about its holdings and requests for specimen loans should, as in the past, be addressed to Dr. Donald F. Hoffmeister, Director, rather than to Mrs. Smith.

NEW BOOK AVAILABLE

The amphibian fauna of Peninsular Malaysia, by P.Y. Berry (1975). x+130 p., 91 text-figures, clothbound, is available for $10.00 postpaid from: International Book Service, 33, Julan 20/16 Petaling Jaya, Selangor, Malaysia.

NOTICE TO COLLECTORS ROUTING THROUGH THE ISTHMUS OF TEHUANTEPEC, MEXICO

Mr. Thomas MacDougall collected plants, mammals, reptiles, amphibians and a few other groups for several decades in Oaxaca and Chiapas, ranging far and wide from his headquarters in Tehuantepec and Oaxaca, before his recent death. His local companions on his forays became quite familiar with collecting and preservation techniques, and would be very glad to collect independently or in company with other field scientists. Arrangements can be made with them through a mutual friend, Sr. Ramon Fosado V., Porfirio Diaz 111, Oaxaca, Oax. (Editor's note: Prospective participants contemplating the above offer should be certain to obtain the necessary U.S. and Mexican collecting permits.)

THE SIGMA XI GRANTS-IN-AID OF RESEARCH AWARDS FOR 1976-77

Lyn C. Branch, Miami University, Oxford, Ohio. Aerobic and anaerobic respiratory strategies of three larval salamanders. $100.

James D. Brandt, Yale University. Ultrastructural studies of the infrared receptors of rattlesnakes. $250.

Daniel R. Brooks. University of Mississippi. Evolutionary history of the digenetic trematodes of crocodilians. $300.

Jonathan A. Campbell, University of Texas at Arlington. The systematics, distribution, and ecology of the middle American highland pit vipers, Bothrops barbouri and B. godmani. $100.

Keith A. Christian, Colorado State University. Determinants of burrow site selection by the Galapagos land iguana. $100.

Deborah T. Crouse, University of Wisconsin. Microhabitat selection and activity levels in the wood frog (Rana sylvatica). $100.

Frank J. Denaro, State University of New York at Stony Brook. An electrophysiological study of the pineal body in Rana temporaria. $100.

Sean D. Farley, College of Idaho, Caldwell. Feeding habits of Uta stansburiana elegans (Yarrow), from the Central Desert of Baja California, Mexico. $100.

William F. Gergits, State University of New York at Albany. Interspecific aggression and territoriality as mechanisms for competitive exclusion in two species of terrestrial salamanders. $100.

Paul E. Hertz, Harvard University. Altitudinal variation in West Indian Anolis lizards. $100.

John B. Iverson, University of Florida. Systematics and ecology of the mud turtles (genus Kinosternon) inhabiting the interior drainage basins of the Mexican plateau. $200.

Cynthia M. Kagarise, University of Michigan. An evolutionary approach to the mating systems and reproductive behavior of two anurans: The Yosemite toad (Bufo canorus) and the black toad (B. exsul). $100.

George M. Labanik, Southern Illinois University. An experimental study of apostatic selection on the mountain dusky salamander, Desmognathus ochrophaeus. $100.

Bradford Lister, University of Massachusetts. Environmental variation and community structure in Anoline lizards. $100.

Mark B. McCune, University of Michigan. Reproductive strategies of the spring peeper. $125.

Mark B. McCune, University of Michigan. Continuation of the research on reproductive strategies of the spring peeper. $100.

Donald A. Merkle, Longwood College, Farmville, Virginia. Genetic

variation in isolates of Plethodon nettingi. $150.

Scott M. Moody, University of Michigan. Consequences of continental drift on the evolutionary history of the lizard family Agamidae. $150.

Stephen D. Parris, Iowa State University. Home range and individual spacing relationships in the marine toad, Bufo marinus. $100.

Jerald H. Reynolds, North Carolina State University. Population dynamics of Cemophora coccinea and Tantilla coronata in southeastern North Carolina. $100.

Raymond E. Sicard, Boston College. Adenylate cyclase activity in the regenerating forelimbs of the adult newt, Notophthalmus viridescens. $100.

Douglas Simmons, University of Florida. Ecological energetics of the American alligator. $50.

E. Eugene Spears, University of Florida. Biochemical systematics in the genus Amphiuma (Urodela). $100.

Kurt Steinwascher, Duke University. Identification of the tadpole intestinal alga and its distribution in North Carolina species. $150.

Myrna E. Watanabe, New York University. The ethology of the American alligator in its natural habitat. $100.

Michael J. Wong, University of California, Los Angeles. An ecological study of the incursion of Sonoran Desert lizards into the Cape region of Baja California, Mexico. $100.

ERRATA

HR 8(3), p. 108, col. 2 (near bottom): M.A. DEL TORO should read M. ALVAREZ DEL TORO.

We wish to acknowledge with gratitude the contributions of the following Contributing and Sustaining Members whose generosity added $870 to our fiscal 1977 income--a sum sufficient to guarantee another Circular!

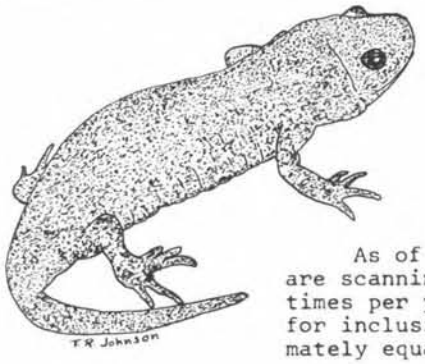
Proposed Amendment to SSAR By-Laws

In accordance with Article IX of the SSAR By-Laws, the SSAR membership is herewith notified that the SSAR Board of Directors has approved the following proposed amendment to the By-Laws:



...that wherever they appear in the SSAR By-Laws, the words "Chairman, Chairman-elect, immediate past Chairman" be changed to "President, President-elect, immediate past President" respectively, said amendment to become effective on 1 January 1979.

The above proposed amendment will be presented and discussed at the Business Meeting during the 21st Annual Meeting of the SSAR at Arizona State University, Tempe, Arizona, from 31 May to 6 June 1978. A ballot will be mailed to the entire SSAR membership within one month following the SSAR Annual Meeting.

Stephen R. Edwards
SSAR Secretary
15 March 1978

Oklahoma has everything for the herpetologist. As well as roads leading to Paris, Texas, we also have our own Frogville. Frogville is in southeastern Choctaw County and dates back to 1897 when it took its name from the great plethora of frogs so large they reputedly "ate young ducks". Photograph by Jeffrey H. Black.

Current Literature

As of January, 1978, approximately 70 searchers are scanning 400 journals. Titles are published four times per year. Searchers are encouraged to submit titles for inclusion at three month intervals to assure approximately equal listings in HR.

Anyone publishing in a journal that is not widely distributed is invited to submit a complete citation or send a reprint to insure that the reference is published in Current Literature. Complete citations to obscure references are also welcome.

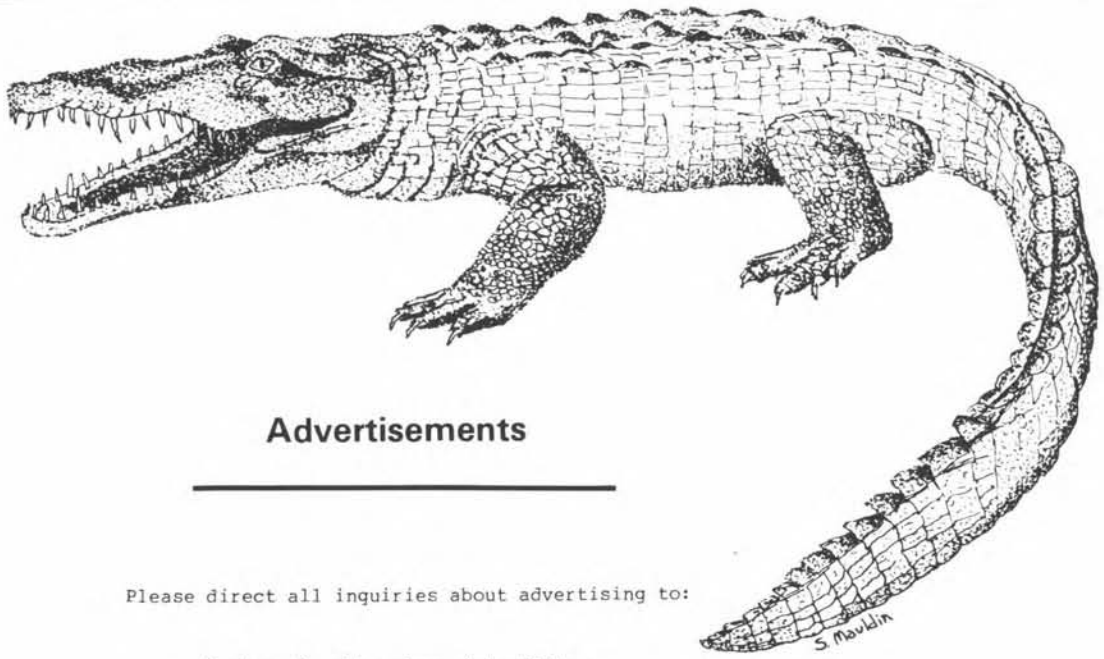
Annual Meeting Symposium: Topics and Participants

During the first week of June, 1978, a joint annual meeting of The Society for the Study of Amphibians and Reptiles (SSAR), Herpetologists' League (HL) and the American Society of Ichthyologists and Herpetologists (ASIH) will be held at Arizona State University in Tempe, Arizona. A symposium dealing with the reproductive biology of captive reptiles will be presented with a volume of the proceedings to follow. The symposium will be divided into two parts: the first will deal with environmental aspects and problems likely to occur with captive reptile populations whereas the second part will address reproductive strategies, behavioral aspects and successful breeding programs, especially concerning endangered species. Some of the participants are as follows: Historical Perspectives: Dr. Roger Conant (University of New Mexico), Captive Maladaption Syndrome: Dr. Daniel Cowan (UTMSH), Temperature and Light: Dr. Philip Regal (University of Minnesota), Viral-Mycotic-Neoplastic Disease Agents: Dr. Elliot Jacobson (University of Florida), Antibiotic Therapy: Dr. Mitchell Bush (National Zoo), Protozoans: Dr. Raymond Napolitano (Bronx Zoo), Helminths: Dr. Dennis Deakins (Scott and White Hospital), Ectoparasites: Dr. Richard Loomis (California State University), Nutrition: Dr. Joseph Bielitzki (Topeka Zoo), Anesthesia: Dr. Emil Dolensek (Bronx Zoo), Radiology and Surgical Techniques: Dr. Michael Herron (Texas A & M University), Post Mortem Evaluation: Dr. Richard Montali (National Zoo), Closing Remarks: Dr. Murray Fowler (University of California, Davis), Reproductive Strategies: Dr. Henry Fitch (University of Kansas), Behavioral Requirements: Dr. Charles Carpenter (University of Oklahoma), Methods for Inducing Reproduction: Drs. David Crews and Leslie Garrick (Harvard University, Bronx Zoo), and Exhibition and Management Techniques: Mr. J. Kevin Bowler (Philadelphia Zoo). Presentations dealing with various breeding programs include: Chinese Alligator: Mr. John Behler (Bronx Zoo), American Alligator: Dr. Ted Joanen (Louisiana Wildlife and Fisheries Commission), Morelet's Crocodile: Mr. R. Howard Hunt (Atlanta Zoo), West African Dwarf Crocodile: Mr. Bern Tryon (Ft. Worth Zoo), Galapagos Tortoise: Dr. James Bacon (San Diego Zoo), Sea Turtles: Dr. David Ehrenfeld (Rutgers University), Gekkonid and Helodermatid Lizards: Mr. Ernie Wagner (Woodland Park Zoo), Boids: Mr. Thomas Huff (Reptile Breeding Foundation), Colubrid Snakes: Dr. Glenn Slemmer (University of British Columbia), and Kingsnakes: Dr. Richard Zweifel (American Museum of Natural History).



Anyone interested in these topics is urged to attend.

COLLECTOR AND IMPORTER OF
RARE AND OUT OF PRINT BOOKS
AND PUBLICATIONS IN THE FIELD
OF HERPETOLOGY AND NATURAL HISTORY

Herpetological books and publications. Old prints, movie stills and postcards in the field of herpetology and natural history. If it has a herpetological subject on it, we handle it. We buy large and small libraries as well as single items. Highest prices paid. Send want list. Free search service. All the following price lists are sent third class. In the event you prefer your list to go airmail, please include $0.54 for U. S. and $1.00 for foreign postage.

HERPETOLOGICAL LIST: 1977 - 1978 issued in two parts.
Part I. Contains A - M. Pages 1 - 24. 2126 items. Price: $2.00
Part II. Contains N - Z. Pages 25 - 43. 1612 items. Price: $2.00

NATURAL HISTORY LIST: 1977 - 1978 contains 3661 items in the following fields: paleontology, geology, mollusks, invertebrates, entomology, general natural history, botany, mammals, birds, fishes, reptiles, and amphibians.

NATURAL HISTORY PRINTS
BY DAVID M. DENNIS

FOR THE FIRST TIME wildlife prints by David M. Dennis are being offered for public sale. These portraits are *full-color reproductions* of the original watercolor drawings, each printed on a sturdy paper stock measuring 20 by 24 inches and suitable for framing. Prints are *strictly limited to an edition of 500 copies, each of which the artist has numbered and signed individually.* Because of the relatively small size of the edition and the fact that this is the first offering of Mr. Dennis' work, these prints represent a sound investment as well as a visual delight. They would also be ideal for gifts.

Mr. Dennis is widely known to the scientific community as a wildlife artist specializing in watercolor portraits of lower vertebrates and insects. His self-taught artistry is complemented by his academic training in biology and his personal field experience with each of the animals he paints. Mr. Dennis earned his undergraduate degree in zoology from The Ohio State University in 1966 and since then he has held a succession of positions as biological illustrator at the Columbus Zoological Gardens, the University of Kansas Museum of Natural History and now at Ohio State. He has illustrated numerous biology textbooks including one which he co-authored, but is perhaps best known to vertebrate biologists for the exquisite series of watercolors published in *Hylid Frogs of Middle America* (The University of Kansas Press, 1970). Originals of Mr. Dennis' watercolors have been exhibited in art galleries and museums throughout the United States and also at numerous scientific meetings.

TO ORDER please use the form provided below:

_____

your name (please print)

_____

address *city* *state* *zip*

Please mark the appropriate boxes and fill in the last column.

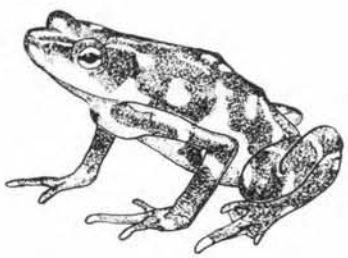
society for the study of amphibians and reptiles

The Society for the Study of Amphibians and Reptiles is a non-profit, international organization established to advance the study of amphibians and reptiles. Although begun in 1958 as a regional society, the SSAR has rapidly gained a world-wide membership. Today it is recognized as having the most diverse society-sponsored program of services and publications for students of herpetology. Membership is open to all persons interested in learning about amphibians and reptiles.

activities



An annual meeting is held each summer on a university campus or at a biological station in the United States. The Society especially wishes to attract students to its meetings by providing inexpensive and informal facilities. In addition to the papers given by members at these meetings, symposia or other invited speakers are usually planned which allow for detailed discussions of important areas of contemporary study. Workshops for regional society representatives have been organized for the purpose of exploring common problems and sharing new ideas. Live animal, photographic, art, and other exhibits are organized, as well as field trips.

The Society makes a concerted effort to involve a diverse segment of its membership in Committee activities designed to further our knowledge of amphibians and reptiles and manage the affairs of the Society. Committees include: Publications, Nominating, Student Prize, Systematic Resources, Common and Scientific Names, Current Literature, Regional Society Liaison, Conservation, Public Affairs, Editorial, Translations, and Annual Meeting.

publications

SSAR sponsors one of the most diversified series of publications of any scientific society. Each series is described on the reverse of this page. Back issues of most publications are available; a detailed price-list can be obtained simply by checking the appropriate box on the membership application.

membership privileges

All persons with an interest in amphibians and reptiles are welcome to become members of SSAR. Members vote on society matters, attend meetings, and participate in other Society activities. Each year members receive the following publications: Journal of Herpetology (4 issues, totaling about 400 pages), Facsimile Reprints in Herpetology (3-4 issues, about 200 pages), Herpetological Circulars (1-2 issues, about 50 pages), and Herpetological Review (4 issues, about 130 pages).

In addition, SSAR members receive a substantial discount on all book-length facsimile reprints issued during the year. Members may also place standing orders for accounts in the SSAR Catalogue of American Amphibians and Reptiles. Those persons electing the higher membership categories (Sustaining and Contributing members) receive the same publications and services, but provide additional financial support which allows the Society to expand and improve its programs more rapidly than would otherwise be possible.

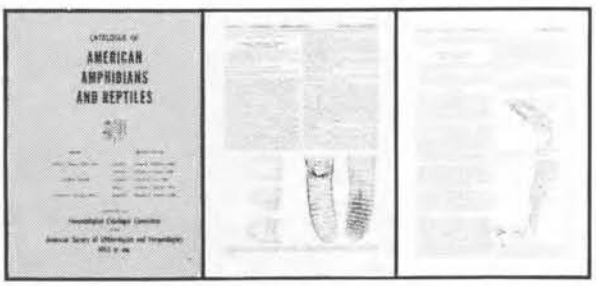
journal of herpetology

The Journal is the Society's official scientific publication. It is international in scope and broadly covers amphibian and reptilian biology. Manuscripts of any length on original research or reviews, whether by members or not, are invited. Most articles are in English and are often extensively illustrated with photographs, drawings and color plates.

herpetological review

Since 1967, Herp Review has been the principal newsletter for the herpetological community. It contains newsnotes about people, institutions, programs and events of interest, including conservation news, book reviews, regional society news, articles on care of captive specimens, and ads.



A primary service of Herp Review is publication of a list of "Current Herpetological Titles" to keep readers abreast of the literature. Titles are obtained from a regular search of hundreds of biological journals by members of the Society.

herpetological circulars

This series started in 1973 and is intended to serve the broadest spectrum of people with an interest in herpetology. Circulars are sent to all members, and may be purchased by museums, clubs hospitals and governmental agencies. Titles of available Circulars include: A Guide to Preservation Techniques for Amphibians and Reptiles; Guia de Tecnicas de Preservacion de Anfibios y Reptiles; Collections of Preserved Amphibians and Reptiles in the United States; A Brief Outline of Suggested Treatments for Diseases of Captive Reptiles; and, Endangered and Threatened Amphibians and Reptiles in the United States.

ssar catalogue of american amphibians and reptiles

The Catalogue is a series of loose-leaf accounts, each giving a wealth of information about a particular genus or species, including common and scientific names, a description, fossil records, a distribution map, and a literature survey. It is an essential reference for all biologists using amphibians and reptiles in research.

To date, over 190 accounts have been issued. Twelve accounts are published each year for $6.00 ($12.00 for institutional subscriptions). This series is not provided as part of the membership; however, standing orders can be made on the SSAR dues form.

facsimile reprints

This series makes available once again important papers and books on amphibians and reptiles; all are exact copies with new introductions, indexes or other features. Members receive the smaller booklets without charge; in the past, authors included were Boulenger, Cope, Eschscholtz, Gray, LeConte, Linnaeus, Tschudi, and Rafinesque.

SSAR also publishes a book-length series; all members receive a special price discount. Titles include: The Bulletin of the Antivenin Institute of America, Camp's Classification of Lizards, Bojanus's Anatome Testudinis, Wiegmann's Herpetolgica Mexicana, Williston's Osteology of Reptiles, Sowerby & Lear's Tortoises, Turtles and Terrapins, Dunn's Salamanders of the Family Plethodontidae, Tschudi's Classification der Batrachier, McIlhaney's The Alligator's Life History, and Holbrook's North American Herpetology.

other publications

Two other series are now discontinued but back issues are still available. Both were published by SSAR's predecessor, The Ohio Herpetological Society. In spite of the Society's geographically-associated name, the scope of these series (Journal, Special Publications) is international in character; all publications are illustrated.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of Herpetological Review in 1967 (Corson Hirschfeld, Editor):

> "Herpetological Review incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the Review will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Now in its tenth year, Herpetological Review remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the Journal of Herpetology -- see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Authors are urged to write the editors before submitting feature-length articles. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles are desired. Submissions should be black-and-white, 8 X 10, glossy prints, and should be accompanied by a descriptive caption and exposure data. The name and address of the contributor should be taped or penciled on the back of each print. Please DO NOT send photographs before corresponding with the editors about them. Return of unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions can be supplied if desired. Contributors will receive ordering information prior to publication of their material. Herpetological Review will accept commercial advertising. Rates and copy information are available from the editors.

Annual Meeting News

SSAR MEETING IN LAWRENCE WELL ATTENDED

The 20th Annual Meeting of the Society for the Study of Amphibians and Reptiles, held at The University of Kansas in Lawrence from 7-13 August 1977, was a huge success. Over 300 herpetologists from throughout the world registered for the meeting, which was held concurrently with the Herpetologists' League's annual get-together.

Socials, symposia, conferences and paper sessions were enthusiastically attended and enjoyed by the participants.

Highlights of the SSAR Business Meeting held on 10 August follow.

Chairman Max Nickerson opened the meeting at 4:30 p.m., noting that the SSAR was in need of volunteers for committee positions and other jobs important to the future development of the Society. Max stated that if the Society was to continue to provide the kinds of services and benefits to its members that it has in the past, it was essential that more members get involved. If you would like to help please contact either Max Nickerson, Chairman or Joe Collins, Chairman-elect.

Treasurer's Report: Henri Seibert stated that the membership had increased by 200 over last year at this time. While the financial status of the Society was sound, Seibert reported that the Board had voted to raise the dues to: $10.00/year for students, and $12.00 /year for regular membership. This increase in dues was dictated because of the desire to provide more services and publications to the members during the forthcoming year. Catalogue accounts will still be prepared at the rate of 15/year at a subscription rate of $6.00/ year.

Nickerson presented Henri Seibert with a leather-bound collection of letters prepared by past and present officers and editors. This presentation was made in gratitude for the services that Henri has provided the Society over the past years. Clearly the SSAR would not be able to provide the level of services it does to its members if we didn't have a treasurer like Henri. His dedicated service to the Society should be recognized by all of the members, not just those few that face the annual challenge of negotiating a new budget. Henri, thanks!!!!

Facsimile Reprints: Kraig Adler reported that in the past year his committee had overseen the publication of two book-length reprints: Holbrook's Herpetology of North America and McIlhenny's Life History of the Alligator. Further, the index to the collected works of Boulenger is now available.

In the future the committee is planning to publish the collected papers of Van DenBergh, Gloyd's Rattlesnakes, Genera Sistrurus and Crotalus, Cope's Batrachia of Central America and Mexico, Espada's Vertebrados del Viaje al Pacifico: Batracios, and Spix's collected works on Brasilian herpetology, and Vol. 3 of Wright and Wright's Handbook of Snakes.

Kraig requested comments and suggestions from the members concerning future facsimile reprints and the direction of the program.

Herpetological Review: George Pisani, Co-editor, reported five issues of Herp. Review may be published during the forthcoming year. If this is necessary, one issue will be dedicated to the Tempe meetings and will carry the abstracts for the papers. Also, during the next year Herp. Review will carry an estimated 2000 citations under Current Titles. George asked that any time members purchase products advertised in Herp Review, they inform the manufacturer that they learned about their product in Herp. Review. This will help sell advertising in the future and help keep the dues at a relatively low level.

Herpetological Circulars: George, as Editor of Herpetological Circulars, noted that during the forthcoming year he hoped that booklets would be published on: Common Names

The herpetological art exhibit held during the meeting was tastefully organized and displayed by Linda Trueb (photograph by Bob Gillum, KU Division of Continuing Education).

Roger Conant surveys with amazement the social antics of his assembled colleagues at the picnic (photograph by Larry Miller).

of Amphibians and Reptiles in North America, Longevity Records of Captive Reptiles, and Albinism in Herps.

Jim Murphy, Chairman of the Regional Society Liaison Committee reported that the Regional Society Conference held in conjunction with these meetings was a fantastic success; more than 70 participants had attended. Further, most people had stated that the experience was very valuable and that if the SSAR sponsored similar conferences in conjunction with their meetings in the future, they would be very interested in attending. Jim also reported that over 30 people from zoos were attending these meetings, and most felt that they were very rewarding.

Janice Perry displays one of the animals from the excellent live exhibit which was set up and sponsored during the meetings by the Kansas Herpetological Society (photograph by Larry Miller).

Jim reported that, because of the growing interest in the SSAR of people from zoological parks, he had proposed a symposium around the theme "Animal Husbandry" for the Tempe meetings next year. The Board of the Society has endorsed this proposal and Jim stated that he will proceed with the arrangements.

Max Nickerson reported that the Nominating Committee had presented the following slate of candidates for the up-coming elections:

Chairman: Ron Altig
Margaret Stewart
Secretary: Stephen Edwards
Treasurer: Henri Seibert
Directors: Jeff Black
Marty Crump
Carl Gans
John Lynch
Richard Wassersug

Max called for nominations from the floor. In the absence of further nominations, it was moved and seconded that the slate of candidates presented by the Nominating Committee be accepted for the forthcoming elections. THE MOTION PASSED UNANIMOUSLY.

Annual Meeting, 1978: Max announced that the SSAR meeting will be held from 31 May through 7 June, 1978 at Arizona State University, Tempe, Arizona. The Herp League and ASIH will also be meeting in Tempe at the same time. This will be the first time that all three herpetological societies have met simultaneously at one site. Jack Fouquette, chairman of the local committee, has made arrangements for dorm space to be available for participants.

Max also reported that the board had approved the meeting site for the 1980 meeting: Milwaukee, Wisconsin; Milwaukee Public Museum, host. The 1979 meeting will be convened at Knoxville, Tennessee with the University of Tennessee serving as host. Sandy Echternacht is the chairman of the local committee.

Student Prize: Meg Stewart, Chairman of the Student Prize Committee reported that George Labanik had been selected as the winner for his paper entitled: "Prey availability, consumption and selection in the cricket frog, Acris crepitans (Amphibia, Anura, Hylidae). Jour. Herpetology 10(4): 293-298. This prize carries a $100.00 award.

Secretary's Report: Steve Edwards reported that during the past year he had successfully completed the paper work for incorporation of the Society in the State of Kansas. With this step completed he hoped that the SSAR could secure a ruling from the IRS concerning its tax status as a non-profit corporation during the next year.

Steve noted that the Society's membership brochure was being redesigned and that copies would be available shortly. Ballots for the forthcoming election should be mailed out by the end of September.

Grants-in-Herpetology. Max reported that the board had requested that he establish a committee to draft the protocol under which a mini-grant program might be established and managed by the SSAR. At present the program is conceived as being similar to the Sigma Xi grant program; however, it would support grants in four areas: Animal Husbandry, Conservation, Regional Societies, and Student Research. This committee will present its recommendations at the Tempe board meeting.

Resolutions Committee: John Iverson, Chairman, presented the following resolution for consideration by those in attendance:

WHEREAS, the University of Kansas, Vice Chancellor William Argersinger, Conference Coordinator Rich-

Edward H. Taylor recounts memories of wilder herpetological meetings he has attended (photograph by Bob Gillum, KU Division of Continuing Education).

Dick Vogt relaxes in the barn at the meeting-sponsored picnic near his special stall (photograph by Larry Miller).

ard Treece, and local committee Chairperson William Duellman have provided generous hospitality in hosting our annual meeting, and

WHEREAS, Linda Trueb, Joe Collins, Henry Fitch, Steve Edwards, George Pisani, Rose Etta Kurtz, Tom Swearingen, Ruth Gennrich, Cathy Dwigans, Eva Hudson, Roberta Eaton, Ruth White, John Bucher, Barbara Paschke, Annie Simpson, Kay Shortridge, Chuck Jones, Sally Cool, Tom Berger, Dave Cannatella, Luis Malaret, Michele Edwards, Julian Lee, Jaime Pefaur, Greg Pregill, Becky Pyles, and Terry Schwaner, of this institution have worked like #@%%, to contribute to the success of the meetings, and

WHEREAS, particular recognition is due Dr. Edward H Taylor, in his capacity as honorary Chairman of the local committee, and more importantly for his outstanding and unselfish contributions to the herpetological community for more than five decades; and,

WHEREAS, Kelly Irwin, Janice Perry, Eric Rundquist, Shelly Skie, Larry Miller, Stan Roth, Marjorie Perry, Scott Palmer, and Andrea Stammler of the Kansas Herpetological Society; Jan Caldwell of the State Biological Survey of Kansas; Robert Clarke and Jim Knight of Emporia State University; David Grow and Peter Gray of Sedgwick County Zoo; and Melissa Burtt, Gary Clarke, and John Wortman of the Topeka Zoo, also deserve recognition for efforts on our behalf, therefore

BE IT RESOLVED, that the SSAR and HL sincerely thank these institutions and persons for a job well done!

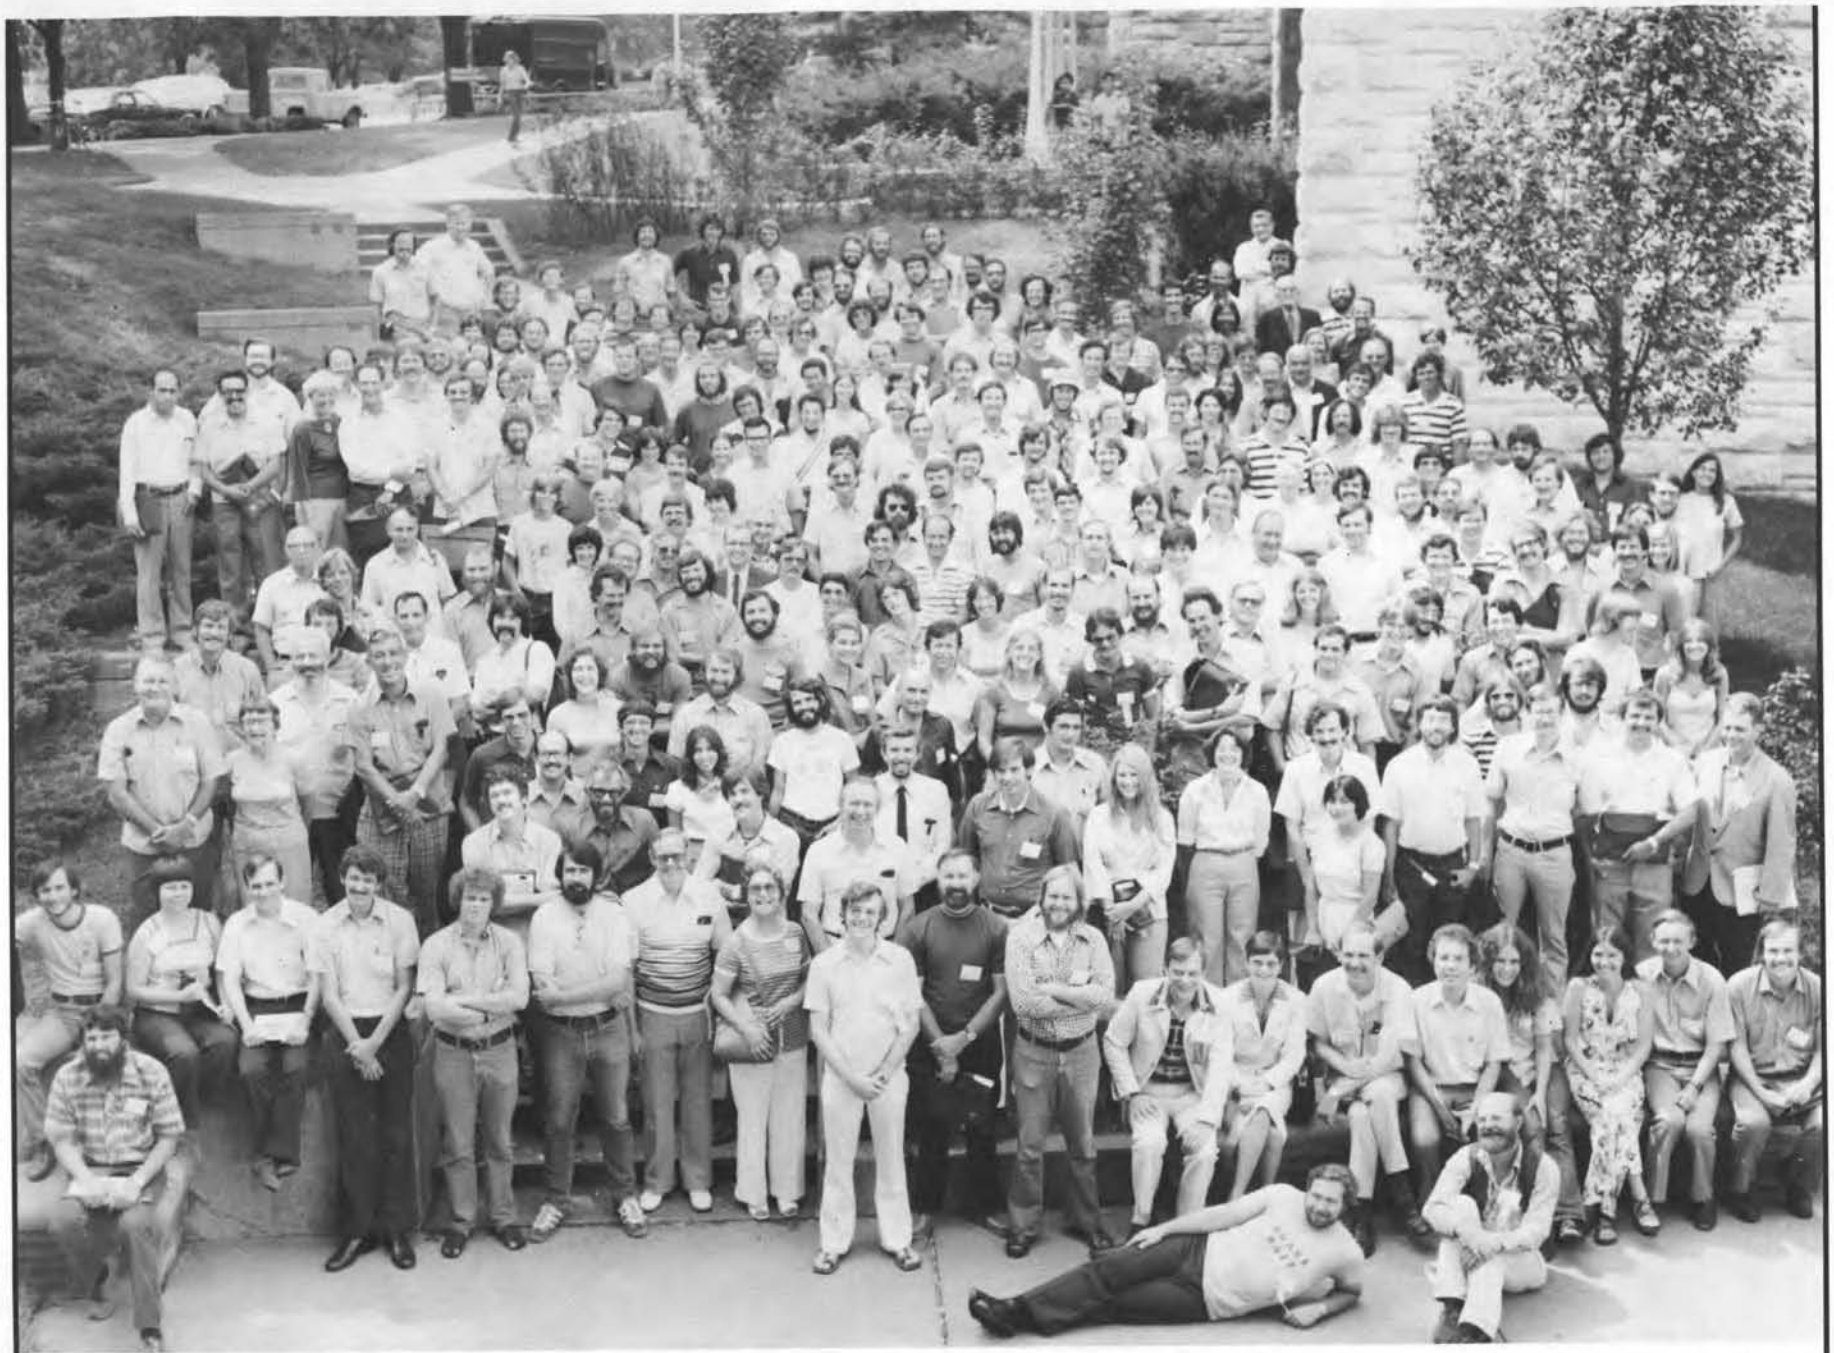
It was moved and seconded to adopt the resolution as presented. THE MOTION PASSED WITH UNANIMOUS APPLAUSE.

In response to a request for comments from the floor it was recommended that in the future the Nominating Committee should give special consideration to non-U.S. citizens for at least one position on the board.

It was also suggested that the Society should look into ways of accumulating lists of student theses that could be made available to the members. The Society for Vertebrate Paleontology supports a similar program that could be used as a model.

With no further comment from the floor, Max Nickerson adjourned the meeting.

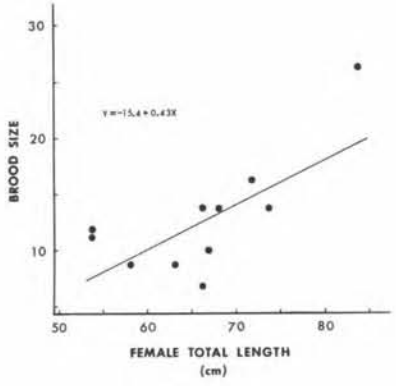
Respectfully submitted,



Stephen R. Edwards
Secretary

John Applegarth is a handsome prince, but Delfi Messinger seems worried about the frog (photograph by Larry Miller).

Participants: Symposium on the South American Herpetofauna: Its origin, evolution, and dispersal. 1st Row (L-R): Alberto Veloso M. (Santiago, Chile), Beryl Simpson (Washington, D.C.), Jaime E. Pefaur (Lawrence, Kansas), Ana Maria Baez (Buenos Aires, Argentina), Jose M. Cei (Mendoza, Argentina). 2nd Row: Lars Brundin (Stockholm, Sweden), Thomas E. Lovejoy (Washington, D.C.), Donn E. Rosen (New York, New York), Jorgen H. Haffer (Wies-baden, Germany), Thomas H. Fritts (San Diego, California), Ramon Formas (Valdivia, Chile), Raymond F. Laurent (Tucuman, Argentina). 3rd Row: William E. Duellman (Lawrence, Kansas), James R. Dixon (College Station, Texas), Marinus S. Hoogmoed (Leiden, Netherlands), John D. Lynch (Lincoln, Nebraska), W. Ronald Heyer (Washington, D.C.), Michael J. Tyler (Adelaide, Australia), Jose M. Gallardo (Buenos Aires, Argentina).



The meeting participants assembled in a natural, unstructured grouping at the north edge of the Museum of Natural History. Persons who did not attend the meeting should note the living trees in the background, proof positive that Kansas is not all wheat and corn fields.

CLUTCH SIZE AND SIZE OF YOUNG IN THE MEXICAN GARTER SNAKE, THAMNOPHIS MELANOGASTER (REPTILIA, SERPENTES, COLUBRIDAE)

Reproductive data from eleven female Mexican garter snakes, Thamnophis melanogaster, from Lago Quitzeo, Michoacan, Mexico were collected while the junior author was studying the courtship behavior of this species. Clutch size and size of young at parturition have not been previously recorded for T. melanogaster although these are known in many other garter snakes (Fitch, 1970).

The reproductive data we collected (Table I) were analysed by linear regression of clutch size and mean total length of young against the females' total lengths (snout vent lengths were unavailable) and mean total length of young versus clutch size. Correlation coefficients from each regression were calculated.

Clutch size showed a high positive correlation with the total length of the female in this species ($r = 0.74$, $P < 0.01$, Fig. 1). This is as expected; the larger the female the larger brood its body can safely produce. A positive correlation of mean size of the young to females' size would indicate that as the female gets larger, fitness is increased by producing larger young rather than just more young. However, though the correlation of the mean length of young of this species with the size of the female is positive, it is not significant at the 0.05 level ($r = 0.54$, $P < 0.08$). The mean size of the young is not correlated at all to the brood size ($r = 0.20$, $P < 0.55$). The significance of the size of young snakes at parturition can not be evaluated here due to the low sample size, but the possibility that larger snakes produce larger young is still a viable hypothesis and should be tested.

A YELLOW ALBINO DESMOGNATHUS FUSCUS FROM WESTERN MASSACHUSETTS

Channel and Valentine (1972) describe an amelanic Desmognathus fuscus from West Virginia. Their description fits closely that of a specimen collected by myself and Steve and JoAnn O'Neil of the Western Massachusetts Herpetological Society, on 13 Oct., 1975 at Mt. Tom, Hampden County, Mass.

The collection site is a seepage area that ranges from a flowing brook in Spring and during heavy rains to a moist, barely moving swamp in mid-summer and during droughts. Many rocks and leaves clog the channel in the predominantly Oak-Hickory forest where D. fuscus is abundant in the wet areas.

Many normally colored specimens were found the same day as the amelanic specimen. Alive, the dorsal coloration is close to Ridgeway's (1886) Tawny (Plate V). In different light, the color is closer to Raw Sienna (Plate V) or Tawny Ochraceous (Plate V). A more precise color description is made by using the Munsell Book of Color (1963) and the Munsell Notation System (Munsell Color Co., Inc., Baltimore). With the specimen under a MacBeth "Lablite" unit (MacBeth Daylighting Corp., Newburgh, N.Y.) and the control set on "Daylight," the value for the overall dorsal coloration is assigned 5YR 5/5, indicating the hue, value, and chroma. At capture, the specimen was 72 mm long (37 mm snout-vent).

Presently (July 1977), the animal is being maintained in a terrarium. Its color has not changed nearly two years after capture. It does not seem to behave differently towards light than the normally colored D. fuscus kept with it.

LEOPARD FROG SUPPLY

The northern leopard frog Rana pipiens has been for many years the principal amphibian used for biomedical research and teaching. Unfortunately, such frogs of northern origin are no longer available in significant quantities and biological supply houses have turned to other regions, notably northwestern Mexico, as a source of frogs. The biology of these Mexican frogs is clearly different from that of the northern R. pipiens, a matter that was extensively discussed at a symposium on the laboratory frog (1), which was attended by major commercial frog suppliers. Recently it has been shown that, in the region of northern Sinaloa, Mexico, where most of these leopard frogs are collected, no R. pipiens are to be found. Instead, there exist two sympatric species of leopard frogs, R. berlandieri forreri and R.magnaocularis (2). Commercial collections made in this area from October through March contain about 80 percent R. berlandieri forreri and 20 percent R. magnaocularis. During other times of the year even fewer R. magnaocularis are found in these collections. Northeastern Mexico has now become an additional source of leopard frogs, and collections from this region are composed of R. berlandieri berlandieri.

For reasons unclear to us, commercial houses are now supplying

Mexican leopard frogs designated as "Rana pipiens berlandieri." This is an unsatisfactory circumstance, not only because of the erroneous nomenclature, but because articles are beginning to appear about research, the meaning of which will be questionable, since the actual species on which the work was done is not known. Of more serious consequence is the fact that some investigators may think that they are working on R. pipiens when actually they are not. If there were no significant physiological differences among the various species of leopard frogs, the error in nomenclature would present no major problem; however, this is not the case. It has been pointed out in one demonstration of such physiological differences that melanophores of frogs of southern origin (R. berlandieri forreri) contain a preponderance of b-adrenergic receptors, while those from northern frogs (R. pipiens) contain mostly a-adrenergic receptors (3). Other physiological differences among leopard frog species include variations in reproductive cycles, in temperature tolerance, and in enzyme composition. The last is well manifested in the heterogeneity of isozyme patterns among leopard frog species (4).

We wish to emphasize that the various leopard frog species possess different biological characteristics that must be considered when they are used for experimentation.

A KYPHOTIC INDIVIDUAL OF LISSEMYS PUNCTATA PUNCTATA (BONNATERRE)

Hump-backed (kyphotic) soft-shelled turtles have been known for many years. In their accounts of such abnormalities in turtles, Gressitt (1937, cited in Smith, 1947) and Smith (1947) noted records in the literature of kyphosis in two Asian and four American turtle species, all of which incidentally belong to the genus Trionyx Geoffroy (Family: Trionychidae). The only other genus in which a deformed carapace has been reported (Cagle, 1954) is Pseudemys (Family: Testudinidae), which is neither a soft-shelled turtle nor is the deformity kyphotic in nature. There is, however, no record of kyphosis in any Indian turtle so far.

A single kyphotic Lissemys punctata punctata, along with five normal individuals, was secured by the junior author at Ranbir-Singh Pura, 24 km south of Jammu, on January 25, 1976, by digging them out of their hibernation holes in a shallow pond. On identification, all the specimens of the catch turned out to be the members of the species L.p. punctata. All the specimens are deposited in the museum of Department of Bio-Sciences, University of Jammu, as Nos. JUBR 36-41 (the kyphotic specimen being No. JUBR 41). The height, length and width of these and 14 other museum specimens (Nos. JUBR 22-35), collected locally, are provided in Table 1. The height of the specimen was determined by measuring the perpendicular distance between the end of the rib opposite the highest elevation and the crest of the elevation. The length of the carapace was measured from anterior to posterior border and the width of the carapace as the maximum transverse dimension.

Lissemys punctata punctata is distinctive in the proportions of its carapace. It is invariably longer than broad (Fig. 1). In a sample of 19 normal specimens (Table 1), the mean length of the carapace is 169.9 mm (range 105-238 mm), the mean width 156.3 mm (range 99-217 mm). The width to length and width to height ratios in the normal individuals are 0.93 (range 0.87-0.95) and 3.1 (range 2.7-3.4) respectively. In the kyphotic individual, on the contrary, the carapace is broader than long, being only 160 mm in length against a width of 175 mm. The afore-said ratios are also different.

The hump in the odd specimen forms a smooth curve in the antero-posterior axis, being maximally elevated around 3rd and 4th neurals. When viewed from in front (Fig. 2), the hump presents two prominent costal swellings, one on either side of the 3rd/4th neurals, where the costal plates appear to be elevated above the general level of the neurals. In transverse sectional view, the lateral curvatures show a sharp and steep gradient of near 50 degrees with the horizontal, whereas, in the antero-posterior axis (Fig. 3),

*Kyphotic individual (JUBR 41).
F=female; M=male.

the hump inclines at an angle of nearly 30 degrees anteriorly and at about half as much posteriorly.

A perusal of the available literature reveals that Gressitt (1937) was the first to record kyphosis in turtles, and that of the seven cases of kyphosis and carapaceal deformity known so far, six pertain to the genus Trionyx (Family: Trionychidae) and only one to Pseudemys (Family: Testudinidae). While there is some doubt whether the testudinid instance is a case of real kyphosis or not, there is none whatsoever about the condition in the trionychid instances.

Among the recorded kyphotic individuals in Trionyx, two are Asian (Trionyx sinensis and T. steindachneri) and the remaining (T. ferox, T. spiniferus, T. muticus, and an unidentified species) are American. The present report is, thus, the third for Asia, first for India, and seventh case for any trionychid. In spite of this seemingly recurrent appearance of kyphosis in the members of the family trionychidae, it cannot be regarded as a peculiarity only to the members of this family, albeit similar instances in other families of turtles are extremely rare (only 12% as per records). It is seemingly a structural change, not a mutation, that appears as a result of some factor to which the members of the family Trionychidae may be more often subjected, irrespective of the species.

While the cause for kyphosis in turtles remains unknown, Williams (1957) hypothesized that late retraction of the yolk and/or excessively large yolk mass retraction may be the causal factor. Further documentation may confirm this proposal, but an apparently more reasonable hypothesis is that of Smith (1947), wherein the costal plates are believed to ankylose distally with the ribs early enough in embryonic life so that any differential in the growth rate between them and the vertebral column is translated into abnormal conditions of the body.

The absence of records of kyphosis in other families of turtles (save for the solitary report of Cagle, 1954), suggests that either (i) a total prenatal mortality accompanies any tendency towards kyphosis in other families, or (ii) other turtles are extremely resistant to the influence of any causal factor responsible for kyphosis in Lissemys or Trionyx.

Moreover, the tendency of only Lissemys and Trionyx to become kyphotic and survive to some length of time even after affliction, may further indicate that, of the various soft-shelled turtles, these two genera may not be genetically as distant as they are commonly regarded.

Fig. 1. A normal individual of Lissemys punctata punctata showing a comparatively depressed shell which is longer than broad (X 2/5).

Fig. 2. Frontal view of the kyphotic individual of L. punctata punctata. The hump shows a mild median and two prominent costal bulgings (X 1/2).

Fig. 3. Lateral view of the abnormal individual to show the gradient of the hump in the anterior and the posterior half (X 1/2).

Table 1 shows the disparity of the proportions of the normal individuals with the abnormal one (Fig. 3), presumably due to kyphosis. Data available at present are insufficient to surmise whether kyphosis is sex limited or not.

Regional Society News

FIRST RHSC A HUGE SUCCESS

Regional herpetological societies from throughout the United Stats had their first joint meeting on 8 August 1977 at The University of Kansas in Lawrence, under the sponsorship of the Kansas Herpetological Society and the Society for the Study of Amphibians and Reptiles (SSAR). SSAR Co-moderators James B. Murphy and Kraig Adler stated that the intent of the meeting was to stimulate communication among these many societies so they may benefit from each other. Kraig Adler introduced special guest Edward H. Taylor, Professor Emeritus of The University of Kansas, who has profoundly influenced herpetology for more than 60 years. SSAR Conference Coordinator Joseph T. Collins explained that development and growth of regional societies in North America is absolutely phenomenal, unmatched anywhere in the world. Presently there are about 50 state and metropolitan herpetological societies, made up primarily of many individuals who have serious, long-term interest in the biology of amphibians and reptiles. A government survey had shown that there are ca. one million herp hobbyists. Thus, it is appropriate for the SSAR to host this First Regional Herpetological Societies Conference (RHSC) because the SSAR began as the regional Ohio Herpetological Society, and therefore has a strong affiliation with regional societies.

The purpose of the RHSC was to enumerate and discuss the problems regional societies encounter, and share information that may lead to solving these problems. With cooperation each society can do more for its members as well as reptiles and amphibians. Invited speakers gave presentations of 5-10 minutes each, followed by discussion.

Kraig Adler, moderating the first session entitled MECHANICS OF RUNNING A REGIONAL SOCIETY, introduced the first speaker, Wayne Seifert (Texas Herpetological Society and Dallas Herpetological Society) speaking about Problems in Forming and Running a Regional Society. Seifert felt there must be communication among the officers to efficiently run a society. A

monthly newsletter can be helpful, information should be sent to the editor, but usually the editor must actively solicit such information, which can be a very time-consuming endeavor. Meetings, regardless of how often they are held, must be regular, and should always meet at the same location to avoid confusion. The officers should meet more often than at scheduled meetings. Determining how much money a society needs comes after determining its goals--try to accumulate a small hedge of excess funds. Do everything first class: a nice newsletter, classy stationery, good refreshments, etc. Avoid allowing one person to do too much by spreading out the duties. Otherwise the society will encounter stress when that person leaves. Procure new membership via newspaper advertising and word of mouth. If the society is good, word gets around. Get tax exempt non-profit organization status to save money in postage, taxes, and to stimulate tax deductable gifts.

Stanley Dyrkacz (Chicago Herpetological Society) speaking on Publications: Newsletters or Scientific Bulletins?, stressed deciding whether or not a publication is needed, and what kind. Newsletters are easier and cheaper to produce than a bulletin. A newsletter can include all kinds of items. A bulletin or journal may be worthwhile if the money is available, but avoid trying to do too much. Be sure that a publication is informative, neat, and professional. A publication represents the society. A bulletin can include natural history data, information on care of animals in captivity, etc. An advantage to publishing in a regional society journal versus a professional journal is that a note or article is published much more quickly with fewer problems. With a good bulletin that is cited in SSAR's Herpetological Review Current Titles Listing, Biological Abstracts and Zoological Record, a society can attract many more good manuscripts, and in turn acquire new corresponding members. But the publications must come out on time and regularly, otherwise members may not renew their subscriptions. Exchange bulletins or newsletters with other societies to disseminate information. Be sure to make these publications available at meetings. Copyright a publication. It only costs $6.00 and makes it look much better. If you need ideas for a good format, copy a well established journal. Support some of the publication cost with classified advertisements. Editors can try to get manuscripts by writing to people who have published previously in their journal and in others. Contact professionals at museums, zoos, and universities. Another technique for getting publishable material is to require meeting speakers to write an abstract of their presentation and publish it. Carefully choose an editor and be sure (s)he does a good job.

Participants in the First SSAR Regional Herpetological Society Conference held at the Museum of Natural History, University of Kansas, Lawrence, on 8 August 1977. From left to right-- First Row: Ray E. Ashton (FlaHS), William Love (FlaHS), Kelly Irwin (KsHS), John Applegarth (New MexHS), Janice Perry (KsHS), Stanley Dyrkacz (ChicagoHS), Tom Vermersch (TexHS), Eugene Rankin (St. LouisHS). Second Row: Herbert S. Harris (MdHS), Malvin Skaroff (PhilaHS & ESHL), Tom R. Johnson (SSAR & St. LouisHS), Eric Rundquist (KsHS), Michael Morton (OklaHS), Robert Bollinger (OklaHS), Randolph Krohmer (St. LouisHS), Scott Wheeler. Third Row: Kraig Adler (SSAR Conference co-moderator), Robert F. Clarke (KsHS president-host regional society), Steve Garber (ConnHS), Veralynne Bosko (NOAH), Delfi Messinger (KsHS), Marjorie Perry (KsHS), Frank Slavens (Pacific NWHS), Carol Brubaker (DallasHS), Wayne Seifert (TexHS & DallasHS), Charles Radcliffe (ColoHS). Fourth Row: Stan Roth (KsHS), Greg Mengden (TexHS), James B. Murphy (SSAR Conference co-moderator), John Groves (MdHS), George Pisani (SSAR & KsHS), Martin J. Rosenberg (NOAH), Judy Black (OklaHS), David Barker (DallasHS), Hugh Quinn (TexHS). Fifth Row: James L. Knight (KsHS), Shelly Skie (KsHS), Larry Miller (KsHS), Joseph Laszlo (TexHS), John Murphy (Chicago HS), Mike Dloogatch (ChicagoHS), Jeffrey Black (OklaHS). Sixth Row: John Zegel (GaHS), Robert Clark (KsHS), Frank Godwin (GaHS), J. T. Collins (SSAR Conference co-ordinator), Max A. Nickerson (SSAR & WiscHS), James Glenn (UtahHL), Peter Black (OklaHS), Andrew Black (OklaHS).

Tom R. Johnson (St. Louis Herpetological Society and SSAR) spoke about Conservation and Education Programs for Regional Societies. It was his feeling that a society cannot have successful conservation projects without educating the public, and education would not be meaningful without stressing the need for conservation. Besides working with the public it is important to keep state and federal authorities informed of conservation goals, keeping in mind that facts are much more valuable than emotion. Wait until information is ready before presenting it. Useful projects for a society might be to publish and make available a checklist of the amphibians and reptiles in your state or metropolitan area, write a booklet about the care of captive herps, or develop talks for schools and clubs. Exhibit animals at places like shopping centers. Donate money to organizations to buy and protect land. Work with the Audubon Society, Sierra Club, and other groups for a common cause, rather than spreading efforts thinly. In such a way it is possible to influence legislation favorably. If a regional society is especially ambitious, it may be possible to produce education-conservation movies.

Marjorie Perry (Kansas Herpetological Society) addressed the RHSC on How to Increase Income. She emphasized having dues that cover general expenses plus a small reserve. You can stimulate contributions through gift memberships, and IRS tax deductable donations if you are a non-profit organization. Sources of additional revenue can be obtained from special projects such as the production of publications printed and distributed in conjunction with other societies such as the SSAR. Sell back issues of your own publication. Budget very carefully, and keep societal money in interest-bearing accounts. Making money at auctions which use live animals is incompatible with conservation goals of many societies.

James B. Murphy moderated the second session entitled CONSERVATION AND CARE OF CAPTIVE ANIMALS, and introduced David G. Barker (Dallas Herpetological Society) who spoke on Live Collecting and Impact on Critical Habitats. Barker's major points were the need for more information about critical habitats,

and the need to learn more about captive maintenance and reproduction of amphibians and reptiles.

Jeffrey H. Black (Oklahoma Herpetological Society) addressed Promotion of Conservation for Herp Fanciers. He discussed the need to stress conservation of herps in order to educate the members of a society. Field trips are helpful in getting people out and showing them what is meant by conservation. Spots on T.V. and radio reach many people. Posters and live animal displays attract many people, and these plus answering questions and making available literature and posters can get across conservation ideals. Pamphlets or larger undertakings about herps in their natural habitat and how to care for them in captivity should be considered. Distribute these to pet shops where they can be given to buyers of reptiles gratis, so they may properly care for their animals. Let people know they should avoid unnecessary collecting.

James L. Glenn (Utah Herpetologist's League) talked about Problems on Maintenance of Captives (Snakebite, and Disease). He emphasized the need to inform society members of available publications on reptile disease and snakebite, and to inform members and petshops on how animals should be kept in captivity.

Malvin Skaroff (Philadelphia Herpetological Society and Eastern Seaboard Herpetologist's League) spoke on Cooperation Among Regional Societies. Skaroff explained that the ESHL is a loose federation of eleven regional societies from Massachusetts to Florida. Each regional society gives monetary support on a voluntary basis. The group sponsors two semi-annual meetings with one of the constituent societies acting as host. One of ESHL's main purposes is the exchange of information via their newsletter, which is sent to representatives of each group, as well as to the SSAR Liaison Committee and various interested herpetologists. Input to the newsletter comes from society bulletins and newsletters (which are also sent to other societies) as well as personal communications to the editor and coordinator, and includes such information as news of people, programs, collection records and legislative proposals.

Ray Ashton, Jr. (Florida Herpetological Society) addressed the topic of Cooperation for Purposes of Public Education. Regional societies should cooperate with local, regional, or state education or governmental agencies in doing such things as: 1) setting up educational workshops for state fish and game officials, park naturalists, 2) assisting school district environmental education programs, 3) setting up traveling programs to visit camps and parks, 4) cooperating with agencies producing herp publications in fish and game magazines for state parks, etc. He stressed cooperation with environmental groups by producing quality information for their newsletters and magazines. Regional societies can select excellent speakers from among their ranks to present programs to such groups. Cooperate with these groups on environmental projects, because often herps are ignored due to lack of information input. Regional societies should provide formal comments on environmental impact statements, and must band together and remain informed and prepared to comment on important environmental topics which involve amphibians and reptiles. All this can be accomplished by each society developing an educational committee or finding a person to head their public education. Regional societies should avoid being just animal oriented and should equally emphasize people orientation.

Herbert S. Harris (Maryland Herpetological Society) lectured on the Establishment of National League of Regional Societies or a National Clearing House. He proposed that all regional societies have a parent group, the Regional League, which in turn would come under a National League. It would be the National League's responsibility to publish a quality scientific journal, while the Regional League and individual societies would publish their bulletins and/or newsletters concentrating on local needs. He felt a national publication would be useful because many of the papers published in the regional journals are of interest to scientists, but with the myriad of regional journals it is too costly to subscribe to them all.

James B. Murphy (SSAR) spoke last and addressed Cooperation Between Regional Societies and the SSAR: Present and Potential Benefits Through Societal Cooperation. He said the SSAR Regional Society Liaison Committee discontinued trying to set up a nationwide speaker bureau because after posting a notice in Herp Review it received very few responses. He stated that the SSAR is pleased that each year there are more zoo professionals joining the society and attending its meetings. He also informed everyone that Tom Johnson receives regional society material and prepares it for inclusion in Herp Review where pages are allotted specifically for information concerning regional societies.

In summary, the SSAR's First Regional Herpetological Society Conference was a huge success. Many excellent talks were given by the regional society representatives, and plenty of time was available, both during breaks and over dinner, to exchange ideas and get to know persons from other societies across the country. In particular, the SSAR thanks Rose Etta Kurtz for her diligent assistance in organizing the conference, and Philip S. Humphrey, Director of the Museum of Natural History, University of Kansas, for graciously permitting us the use of the Museum's facilities.

The assembled representatives endorsed the idea of the SSAR sponsoring the Second Regional Herpetological Society Conference, to be held in conjunction with the 21st annual meeting of the SSAR in 1978 at Arizona State University in Tempe. This meeting will be held near or over the Memorial Day weekend. Joseph T. Collins volunteered to again act as the conference coordinator, and will contact each regional society soon.

STEVEN D. GARBER, Museum of Natural History, University of Kansas, Lawrence, Kansas 66045 (formerly representing the Connecticut Herpetological Society). ●

FRENCH HERPETOLOGICAL SOCIETY

The French Herpetological Society is active since 1970. Membership includes both Professional and Amateur Herpetologists and amounts to approximately 500 members now. A quarterly international newsletter is published and local and general meetings are held each year in connection with other European Herpetological Societies.

Current projects include accurate mapping of all French species and emphasis is put on protection of endangered species in France and overseas. For further information write to: Dr. J. Castanet, Societe Herpetologique de France, Laboratoire d'anatomie comparee, 2 Place Jessieu, 75005 Paris, France. The yearly dues for membership are $10.00. FOREIGN MEMBERSHIP WELCOME. ●

We wish to acknowledge the generous contributions of the following corporations to the annual meetings of the SSAR and HL:

Mr. Paul B. Huenemann
Library Bureau
Univac Building, Suite 473
1025 Ashworth Road
West Des Moines, Iowa 50265

Mr. Arley Allen
Allen Press
1041 New Hampshire
Lawrence, Kansas 66044

Membership is open to people of all ages who are interested in herpetology. This application, together with a check in the appropriate amount made payable to NOAH, may be submitted to the Treasurer at any monthly meeting or mailed to: NOAH, Department of Biology, Case Western Reserve University, Cleveland, Ohio 44106. Further information may be obtained by calling 216/368-3558 between 9 a.m. and 5 p.m. weekdays.

KERATOPHAGY IN THE SLENDER VINE SNAKE, UROMACER OXYRHYNCHUS

Keratophagy, the eating of shed epidermal material, has previously been reported for several species of snakes (Mattlin, 1946; Groves, 1964; Groves and Groves, 1972). Although this behavior in snakes has been suggested to be related to reptile-eating and/or cannibalistic habits, it appears to be more accidental in occurence than a well developed habit (Groves and Groves, 1972). Reported here is an additional case of keratophagy in a colubrid snake, which supports this latter view.

An adult pair of slender vine snakes, Uromacer oxyrhynchus have been kept together on exhibit at the Philadelphia Zoological Garden for 14 years. These snakes are fed exclusively Anolis carolinensis, which are present in the exhibit at all times. During the night of 25 March 1977, the male shed its skin. The next morning, before the exhibit was cleaned, this snake was observed ingesting part of this skin, beginning approximately 25 cm from the tail, breaking off this piece, and then ingesting it in its entirety, a process which required about 20 minutes. The circumstances which elicited this behavior were not observed.

In June 1976, Bruce Mayer, a keeper in the Reptile House, reported that the female in this exhibit struck at a paper towel while he was cleaning the glass of their exhibit and ingested a piece of it. The stools of this snake were examined and the missing piece of paper towel was found intact about one week later. Our observations on the feeding behavior of this species indicate that they are attracted to prey primarily by movement, since inactive and dead anoles are frequently overlooked even when these snakes are actively searching for food. It is therefore possible that these snakes were first attracted to the paper towel and the shed skin as a result of the movement. In the latter case, it is possible that an anole or even the snake itself could have moved the skin and the snake could have mistaken this movement for the movement of potential prey. The initial seizing of the paper towel and the ingesting of both the piece of paper towel and the shed skin were certainly deliberate.

Although all of the snakes that have been reported to eat shed epidermal material, with the possible exception of Boiga blandingi, are predominantely reptile-eating species, there appears to be no evidence that this behavior occurs frequently and has any significance in their survival. The fact that shed skins are regularly removed from the cages of Uromacer and the observations concerning the ingestion of inorganic matter by one of these snakes, support the view of Groves and Groves (1972) that keratophagic habits in snakes are nothing more than a mere quirk, possibly influenced by reptile-eating tendencies.

We would like to thank Bruce Mayer and Joseph Meenan for their comments on the behavior of these snakes at the Philadelphia Zoological Garden. We would also like to thank Kevin Bowler, Harry Greene, and Frank Groves for their aid in the preparation of this manuscript.

A PROPAGATION PROGRAM FOR CHINESE ALLIGATORS (ALLIGATOR SINENSIS) IN CAPTIVITY

Available information on the wild status of Alligator sinensis is scarce (Honegger, 1968). In the past, the species occurred throughout most of Eastern China. Currently, it is reported in the vicinity of Wuhu in Anhwei Province, Changhsing in Chekiang, and along a small section of the lower reaches of the Yangtze River (Wang Yang, 1962). The present restricted distribution is thought to have resulted from a combination of man-caused habitat alteration and heavy hunting pressure. Although the Chinese alligator is totally protected in the People's Republic of China (A.F. Oeming, in lit.), we can presume that human population pressure will further limit its distribution.

Duplaix-Hall (1975) reports that a total of 59 specimens (11.10.38) are maintained in 38 zoological park collections worldwide. Only six specimens (2.4) are living in zoological collections in the United States. Until recently, these specimens were scattered among five institutions.

After many years of unsuccessful attempts at breeding its pair of Chinese alligators in its Reptile House, the New York Zoological Society searched for a quasi-natural site at which to develop a propagation program. Additional specimens were sought from other zoological parks to include in the project.

The Rockefeller Wildlife Refuge, owned and operated by the Louisiana Wildlife and Fisheries Commission, and located in the coastal marshes of southwestern Louisiana, offers suitable conditions. Comparison of meterological data from the two localities indicates roughly similar temperatures, amounts of precipitation, and seasonal changes. The staff of the Refuge contains some of the most knowledgeable and experienced biologists now studying the ecology, behavior, and reproductive biology of the American alligator (A. mississippiensis). Their programs include the propagation of that species in captivity. Their knowledge and experience is a valuable asset to the A. sinensis propagation effort. The New York Zoological Society submitted a proposal for a joint propagation program to the Louisiana Wildlife and Fisheries Commission. It was approved in late November 1975 and construction of facilities at the Refuge began immediately under the direction of Ted Joanen, Research Leader, Refuge Division. The U.S. National Zoological Park joined the

project by contributing the only other available pair of Chinese alligators in the United States.

On 22 March 1976, the four A. sinensis were transferred from the New York Zoological Park to their quarters at the Rockefeller Wildlife Refuge. Currently, each pair is located in a double-fenced, escape-proof, one-half acre enclosure. Each enclosure contains natural vegetation, two freshwater 400 square foot ponds, and one 1875 square foot (25' x 75') pond. All ponds are graded to a maximum depth of 5 feet. Maintenance of the four specimens will parallel that developed for American alligators currently being bred at the Refuge.

The specimens that are being used in the initial phase of the program are long-term captives. The U.S. National Zoo pair has been in captivity for at least 37 years and the NYZS pair for 19 years. Hopefully, the pairs are still capable of reproduction. Courtship by the NYZS pair has been observed regularly each year, but they have failed to nest. Similar behavior has been demonstrated by the NZP pair. If geriatric problems occur, additional specimens will be sought.

Geographic Distribution

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same. The standard format for a geographic distribution record is:

Scientific name (common name) as it appears in Conant (1956, 1975) or Stebbins (1966). Locality (use metric for distances). Date and collector(s). Identified or verified by. Place of deposition and catalogue number. Comments. Citation. Submitted by (give name and address).

Please submit new geographic distribution records in the standard format only to Joseph C. Mitchell, Graduate Program in Ecology, University of Tennessee, Knoxville, Tennessee 37916. Short manuscripts are acceptable when data cannot be adequately presented in the standard format.

Recommended citation for new geographic distribution records appearing in Herpetological Review is: Jones, J. 1977. Geographic distribution: Rana pipiens. SSAR Herp. Review 8(1): 1.

RANGE EXTENSIONS AND NEW COUNTY RECORDS OF SOME ILLINOIS AMPHIBIANS AND REPTILES

The specimens cited below are in the collection of Harlan D. Walley (HDW), and supplement those Illinois records of Smith (1961, Amphibians and Reptiles of Illinois Nat. Hist. Survey Bull. 28(1): 1-298).

Notophthalmus viridescens louisianensis (Central Newt). DeKalb Co: Audubon Sanctuary Pond. 16 km N DeKalb 15 Feb. 1969-20 March 1969. HDW 725-729. Constitutes a relictual population, and fills the hiatus between the DuPage County record on the east and Lee County on the west. Emydoidea blandingi (Blanding's Turtle). DeKalb Co: 3.2 km W Sandwich, marsh bordering Somonauk Creek. Two specimens observed but not collected 29 April 1972. LaSalle Co: 4.8 km N Sheridan. June 1972. 3.2 km N Utica, Triumph Rd. HDW 1360. Utica record extends range approx. 96.0 km SW Kane County record and 84.8 km NE of Peoria record. Chrysemys scripta elegans (Red-eared Turtle). DeKalb Co: 3.2 km W Sandwich, marsh bordering Somonauk Creek. 29 April 1972. HDW 1219. Extends range 68.6 km NE, 86.4 km E, and 68.8 km W of nearest records. Lake Co: Fox Lake, Pistakee Lake. 14 Sept. 1974. Extends range 9.6 km N of previous Illinois records. Heterodon platyrhinos (Eastern Hog-nose snake). Knox Co: Maquon. 7 Sept. 1970. HDW 1100. Grundy Co: Coal City. 12 July 1974. HDW 1359. Opheodrys vernalis blanchardi (Western Smooth Green Snake). DeKalb Co: 9.6 km S DeKalb, under railroad ties bordering tracks. 15 Sept. 1972. HDW 1233, and five eggs, hatched same day, HDW 1229-1231. Extends range 57.6 km NW, 75.2 km NE and 38.4 km S of previously known localities.

HARLAN D. WALLEY, Department of Biology, Northern Illinois University, DeKalb, Illinois 60115.

THE PRESENCE OF THE SCARLET KINGSNAKE, LAMPROPELTIS TRIANGULUM ELAPSOIDES HOLBROOK (REPTILIA, SERPENTES, COLUBRIDAE), IN THE FLORIDA KEYS

For the past 48 years, the presence of Lampropeltis triangulum in the Florida keys has rested upon one specimen (UMMZ 67741) collected on Key West before or during 1929. Duellman and Schwartz (1958:304) considered this record "doubtful" because, "despite intensive collecting" in the keys, no additional specimens were available. In a more recent listing of snakes inhabiting the Florida keys, Paulson (1966) omitted L. triangulum completely. Williams (1970) examined the specimen and included Key West on his distribution map but listed it as Dade rather than Monroe County. Conant (1975) is the most recent authority to include Key West in the distribution of the species.

On the evening of 29 November 1976, Brian Sharp and I collected an adult male L.t. elapsoides (USNM 204238) 21.3 km NE of Key Largo on Largo Key, Monroe Co., Florida. This locality lies within a Black Ironwood (Krugiodendron fereum) dominated tropical hardwood hammock with a substrate of coral-limestone and scattered loose rock.

Williams (1970) illustrates variation in ventral counts for L. triangulum in which a cline is demonstrated along the Atlantic coast. Ventral counts decrease in a southward direction from New Jersey to Florida with a mean of 170.7 (N=22) in south Florida males. USNM 204238 from Largo Key exhibits a very low ventral count (157) and probably represents the terminus of that cline. The relatively high number of ventrals (176) on UMMZ 67741 from key West tends to relate it to populations farther north. Coluber constrictor (Auffenberg, 1955) and Storeria dekayi (Paulson, 1966) occuring on the lower keys have also been shown to exhibit affinities closer to northern populations than to the less-distant southern mainland. Paulson (1966) discussed the possible significance of this character displacement.

Although the Key West specimen is probably valid, it is doubtful whether L. triangulum still occurs on the heavily developed island. It is possible that this small, secretive, and largely noctural snake has been overlooked on other keys by collectors. Keys which support extensive pineland and/or hammock vegetation, may provide sufficient habitat for the species.

In light of the above evidence, Lampropeltis triangulum should now

be included in all faunal lists of the upper Florida keys.

Acknowledgments

I thank Brian Sharp for valuable field assistance, George R. Zug of the Division of Reptiles, National Museum of Natural History, for the use of facilities, and especially Stephen D. Busack, National Fish and Wildlife Lab, for general assistance. The UMMZ specimen was made available to Busack through R.A. Nussbaum and data were supplied through the efforts of P.E. Feaver.

DISTRIBUTIONAL MAPS OF REPTILES OF IRAN

Map I: Sauria
Map II: Ophidia, Chelonia, Crocodilia

Two distributional maps of Iranian reptiles were prepared using our collections and the literature. Our studies were conducted in 1974 and 1975 throughout Iran. The purposes of these geographic distribution maps are:

1) To enumerate taxa collected during our survey, to subspecies if possible. Unidentified species are included by genera.

2) To serve as a basis for examining the isolation of races, both as a foundation for further recording of the Iranian herpetofauna and as an aid for the field herpetologist to facilitate identification.

Only records of exact localities were used and many regions have not yet been researched herpetologically.

Unique symbols are used for each taxon. By variation of the significant fundamental symbols, the different taxa are linked hierarchically (for example, all Scincidae are listed by a square basic symbol, all members of the genus Eremias by a rhombus). A detailed index of literature refers to all sources used for this revision.

I would be thankful for receipt of other documented records to supplement those of this paper.

Footnote: Agama caucasica mucrohata has been regarded as a synonym of Agama erythrogastra in the sense of Clark, R.J. et al., 1966.

PROJECTO VENEZOLANO SOBRE COCODRILOS (VENEZUELAN CROCODILE PROJECT)

Hoy en dia existe en Venezuela un lugar destinado a servir como centro de investigacion y demonstracion de la Naturaleza: es el Parque Loefling (Puerto Ordaz), el cual se utilizara como sitio donde se efectuara un proceso educativo sobre la interpretacion de la naturaleza y los ciclos biologicos que en ella se cumplen. Uno de los intereses fundamentales de este parque es fomentar trabajos cientificos dirigidos e estudiantes de educacion media. Diez hectareas en estado semivirgen se han comprometido para esta experiencia, donde se encuentran algunos animales autoctonos de la region, representativos de la fauna Guayanesa y sus alrededores. Entre dichos animales esta Crocodylus intermedius, llamado en nuestro medio "Caiman del Orinoco," que fue victima del rios. La historia de los ejemplares que se tienen en el Parque Loefling es la siguiente: Por los anos 1959-1960, fueron recogidos en el Delta del Orinoco 4 cocodrilos (2 hembras y 2 machos) que se trasladaron a un sitio llamado Macagua, cercano a Cuidad Guayana, y mas tarde a una laguna ubicada en el Parque Chachamay. Durante varios anos las crias se perdian. En el ano 1974 las 2 hembras dieron un total de 56 crias. En el mismo ano se escapo uno de los machos progenitores. De los recien nacidos que fueron transladados al Parque Loefling se escaparon 31 y murieron 7 quedondo tan solo 18. Luego murio el otro macho progenitor pero despues de haber prenado a un cocodrilo hambra. Las crias resultantes se recogieron en abril de 1976. De 8 retonos murieron dos. En el presente contamos con 2 hembras progenitoras, 18 individuos de la primera cria (en los que no se ha determinado el sexo) y 5 machos y 1 hembra de la segundra cria, lo cual totaliza 26 ejemplares. Se ha observado que el desove ocurre en el mes de febrero y necesitan arena para que esto ocurra. Actualmente se alimentan a base de carne (bofe) una vez a la semana.

Para el proximo and se lanea A expandir las facilidades para N habilitar una procion destinada a la reproduccion y cria de los ejemplares disponibles, que eventualamente se utilizaran para repoblar las areas donde los cocodrilos antes fueron comunes.

The Parque Loefling (Puerto Ordaz, Venezuela) is being developed as a center for investigation and wildlife demonstration. An educational program is being developed in order to teach an understanding of wildlife and ecological principles. A fundamental interest at the park is to direct scientific studies carried out by high school students. Ten hectares of the park are in a semi-virgin state and will be used for educational purposes. In this area have been released representatives of the fauna of the Venezuelan Guayana and the surrounding areas. Among these animals are Crocodylus intermedius, called in this area "Caiman del Orinoco", a species which was the victum of extermination in recent years and is now seldom found in our rivers. The history of these crocodiles is as follows: In the years 1959-1960 four crocodiles (two males and two females) were collected in the Orinoco Delta, and were taken to a nearby site called Macagua. They were later transferred to a lagoon in the Parque Cachamay (which includes the new Parque Loefling). For some years the broods were lost. In 1974 the two females produced a total of 56 young. The same year one of the adult males escaped. Of the hatchlings that were transferred to the Parque Loefling 31 escaped and 7 died leaving only 18. Later the other adult male died after impregnating one of the females. The resultant brood was collected in April 1976, and of 8 hatchlings, two died. The current population consists of two adult females, 18 young from the first brood (whose sex we have not determined) and five males and one female from the second brood, a total of 26 individuals. Egg laying has been observed to occur in February and the eggs are laid in sand. The animals are fed on bovine lung once a week.

Next year it is planned to expand the facilities in order to make a sector specifically for the reproduction and raising of available crocodiles. The excess specimens will eventually be used to repopulate areas where these crocodiles used to be common.

YOLANDA RAMIREZ and CARMEN CECILIA CASTILLO, Div. Desarollo Humano, Edificio CVG-EDELCA, Apartados 292-301, Ciudad Guayana, Estado Bolivar, Venezuela; and S. J. GORZULA, Dep. Med. Exp., I.V.I.C., Apartado 1827, Caracas 101, Venezuela.

LEGISLATION

Rulemaking actions:

In a final rulemaking issued by the Fish and Wildlife Service (21 July 1977), the giant anole (Anolis roosevelti) has been listed as Endangered and its limited range (mountain forest on the slopes of Mt. Ruaca-Culebra Island, Commonwealth of Puerto Rico) has been designated as Critical Habitat.

Threatened status has been proposed by the U.S. Fish and Wildlife Service for the eastern indigo snake (Drymarchon corais couperi) (1 August 1977). In recent years local populations of the eastern indigo have suffered a major

decline, principally because of commercial trade. The snake's large size and extremely docile nature make it highly desirable as a pet, and "prime" specimens may sell for as much as $250.00 each. The deadline for submitting relevant comments and criticisms regarding the proposed rulemaking to the Fish and Wildlife Service was 30 October 1977.

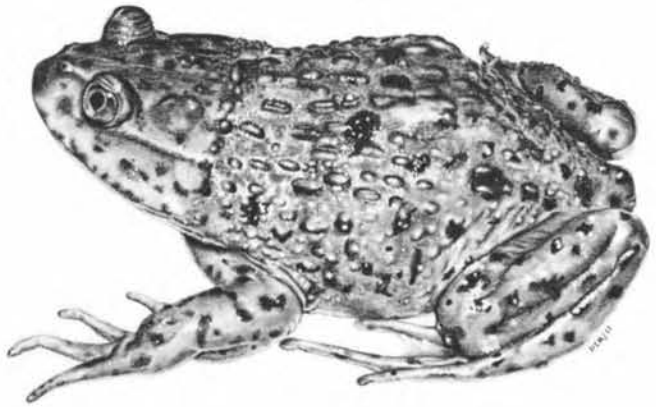
Other herp species whose status is, or recently has been, the subject of Fish and Wildlife rulemakings include: Ameiva polops, Cyclura, stejnegeri, Crotalus willardi obscurus, Epicrates monensis, Natrix fasciata taeniata, Typhlops monensis, Bufo houstonensis, B. lemur, B. nelsonii, Hyla anderson, Rana onca, Necturus lewisi, Eurycea nana, E. troglodytes, Plethodon larselli, P. stormi, Typhlomolge tridentifera, Chrysemys alabamensis, C. concinna suwanniensis, C. rubriventris, Graptemys caglei, G. flavimaculata, G. oculifera, G. pseudogeographica sabinensis, G. versa, G. nigrinoda, Kinosternon bauri bauri, K. flavescens spooneri, and Sternotherus depressus.

Additional notes: Representatives from the nations cooperating in the control of trade in endangered species held a special working session 17-28 October 1977 at Geneva, Switzerland. The discussions covered guidelines for the shipment of live specimens, identification of specimens, exchange of museum specimens, and the care and disposal of confiscated wildlife. There was also a review of certain species listed in Appendices I and II of the Convention on International Trade in Endangered Species. Recommendations were drawn up for action at the next full meeting of the treaty nations, scheduled for fall, 1978 in Costa Rica.

THOMAS J. BERGER, Museum of Natural History, The University of Kansas, Lawrence, Kansas 66045.

News Notes

HERPETOLOGICAL NEWS AT THE SMITHSONIAN



Effective 1 September 1977, George R. Zug became the Chairman of the Department of Vertebrate Zoology, National Museum of Natural History. The chairmanship is a five year term. Dolores Icarangal, the long-time secretary of the Division of Reptiles and Amphibians, has retired. The current staff of the Division consists of Ronald I. Crombie, Ron Heyer, Frances I. McCullough, and Dorsey Williams. Francis Blasdell is assigned to the Division as a cataloguer.

The Herpetology Section of the National Fish and Wildlife Laboratory of the Department of Interior has been reorganized. Bruce Bury transferrd to the laboratory in Fort Collins, Colorado in February 1977. The curatorial position at the Smithsonian is currently unfilled. Steve Busack is the only NFWL staff member currently assigned to divisional duties.

Our sound analysis laboratory is now completed. The basic components of the system are a Kay Sonagraph, a B and K frequency analyzer, and a Hewlett-Packard oscilloscope and strip chart recorder. The system was designed by George Drewry and Ian Straughan and assembled by George Drewry. Anyone interested in using the equipment or having analyses done should contact Heyer. Current understaffing may prevent extensive service to the herpetological community, although contract employees are available for anyone having funds.

Ian Straughan has deposited all data associated with his dissertation on the systematics and species isolating mechanisms of Queensland, Australian frogs in the Division. The materials include tape recordings of Queensland frogs, records of the specimens examined in museums for the dissertation and specimens examined in North American museums after the dissertation was completed. Ian does not plan to publish the systematic portion of his dissertation, but wishes to make the material available to interested workers.

The Smithsonian Herpetological Information Services (SHIS) series continues to be produced and distributed by the Division. Fran McCullough has assumed the editorship of this series; any inquiries concerning the series should be directed to her.

Richard James Holub
(1945-1977)

On 23 August 1977, Richard James Holub died instantly from injuries sustained in an automobile accident in Vernon, New Jersey. Mr. Holub was 32 years old. Best known among amateur and professional herpetologists for his meticulous and thorough studies with Clemmys muhlenbergi, Richard Holub was, by profession, a land surveyor with High Point Engineers in Vernon, New Jersey.

Although never published, Richard's work with the Bog Turtle was well known and much respected. His opinions and knowledge of the species, resulting always from first hand observations, were often sought after by turtle fanciers, professional herpetologists and conservationists alike. He was one of the first people to successfully breed and raise Bog Turtles in captivity and he successfully maintained an outdoor captive breeding colony for a number of years on the farm where he lived in Sussex County, New Jersey.

With an avid interest in herptiles even as a boy in Ridgewood, New Jersey, Mr. Holub continued this interest and broadened it to include all wildlife in his later years. With his wife Susan and their little boy, Michael, Richard was a familiar sight in the fields and woodlands of northern New Jersey during herptile society field trips.

A wildlife photographer and artist in his spare time, Richard was a dedicated conservationist who looked to the day when mankind would learn to share the world with wildlife, respecting animals' right to live out their lives undisturbed. He not only expresed these beliefs, if asked his opinion, but through his actions, truly practiced his beliefs.

One of the initial members of The Muhlenberg Group, Mr. Holub was, at the time of his death, Vice President of the Association for the Conservation of Turtles and Tortoises Inc.

He is survived by his wife Susan and his 7 year old son, Michael. ●

SSAR PRIZE FOR BEST STUDENT JOURNAL PAPER

The Society for the Study of Amphibians and Reptiles awards an annual prize of $100 for the most significant student paper published in each volume of the Journal of Herpetology. Papers must be submitted to the Editor for publication within one year of the author's having been a student at an accredited school (elementary, secondary or university level). Unlike awards for oral presentations, which require the presence of the person at a particular meeting site in order to compete, this prize is open to students throughout the world. Papers are judged by a committee of five persons, international in composition. The Editor must be notified of the student status of the author when the paper is accepted for publication. The award is presented at the Society's Annual Meeting, and it is hoped that each year recipients will be present to accept the award.

The SSAR student prize for the most significant paper published in 1976 appeared in Volume 10 Number 4, pp. 293-298, of the SSAR Journal of Herpetology. The paper, entitled "Prey availability, consumption and selection in the cricket frog, Acris crepitans (Amphibia, Anura, Hylidae)" was written by George M. Labanick, a graduate student in the Department of Zoology, Southern Illinois University, Carbondale. Mr. Labanick's research for the paper was done toward obtaining a Master's thesis, and was conducted under the direction of Dr. John Whitaker.

THE THEODORE ROOSEVELT MEMORIAL FUND

The Theodore Roosevelt Memorial Fund provides financial assistance to individuals (especially graduate students and persons with recent graduate degrees) conducting research in North America in any phase of wildlife conservation or natural history related to the activities of the American Museum of Natural History. Grants are usually kept to small sums of not more than several hundred dollars. Most awards support field work, and funds are not made available for salaries or for the purchase of non-expendable equipment. Address requests for application forms and all correspondence to: Theodore Roosevelt Memorial Fund, The American Museum of Natural History, Central Park West at 79th Street, New York, New York 10024. Deadline for applications is 15 February.

HR EDITORS AND STAFF ARE GRATEFUL

With this last issue of Volume 8, the editors and staff of Herpetological Review wish to express their sincere appreciation to the many individuals whose efforts have made production of this periodical so much easier.

For refereeing articles we thank: Kevin Bowler, Charles C. Carpenter, Henry Fitch, Neil Ford, Richard Franz, Tom R. Johnson, James D. Lazell, Jr., Joseph C. Mitchell, Richard R. Montanucci, James B. Murphy, Jaime Pefaur and Hobart M. Smith.

Special thanks are due Tom R. Johnson, W.F. Nelson, Pat Latas, and Richard Lattis for the fine line drawings they have made available to us. Janice Perry, Eric M. Rundquist and Rose Etta Kurtz have assisted the editors by helping with the innumerable tasks associated with production.

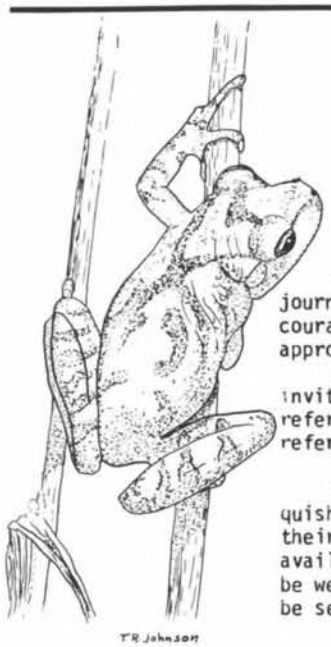
Finally, we thank Philip S. Humphrey, William E. Duellman, Frank B. Cross, E. O. Wiley, all of the Museum of Natural History at the University of Kansas, and Stephen R. Edwards, Association of Systematics Collections, for their logistical support and use of facilities without which Herpetological Review could not be produced.

Bullfrog on a lily pad at Oklahoma City Zoo. Photograph by Jeffrey H. Black.

COLLINS ON LEAVE DURING 1978

J.T. Collins, Co-Editor of HR and SSAR Chairman-elect during 1977, will be on leave from his HR co-editorship during calendar year 1978 since he will be SSAR Chairman that year. Collins will resume co-editorship of HR for calendar 1979. During 1978, all manuscripts, news notes, errata, etc., should be directed to: George R. Pisani, Department of Biology, University of Kansas, Lawrence, Kansas 66045.

The HR co-editors are pleased to announce that, effective 1 January 1978, Sally Cool will become assistant editor for HR, and Barbara Paschke will become associate editor for HR. Mss. Cool and Paschke have given much time and service to the production of HR.



ERRATA

Herp. Review 8(1): p. 13, col. 2, para. 3, line 5: "313v." should read "elev."

Herp Review 8(3): p. 80, col. 3, para. 1, line 28: "contract" should read "contrast."

ELECTION RESULTS

Meg Stewart, Chairperson-Elect
Henri Seibert, Treasurer
Stephen R. Edwards, Secretary
Marty Crump, Director
Carl Gans, Director

Current Literature

As of January, 1977, approximately 70 searchers are scanning 400 journals. Titles are published four times per year. Searchers are encouraged to submit titles for inclusion at three month intervals to assure approximately equal listings in HR.

Anyone publishing in a journal that is not widely distributed is invited to submit a complete citation or send a reprint to insure that the reference is published in Current Literature. Complete citations to obscure references are also welcome.

SEARCHERS NEEDED. In recent months several searchers have had to relinquish their commitment to Current Literature because of increased demands on their time. A number of journals are presently not being scanned and are available for reassignment to anyone who is willing to help. Volunteers will be welcome. All correspondence concerning the Current Literature project should be sent to

POSITION AVAILABLE

DEPARTMENT OF ZOOLOGY
AND
MUSEUM OF VERTEBRATE ZOOLOGY

UNIVERSITY OF CALIFORNIA, BERKELEY

A joint position is available for an advanced Assistant or beginning level Associate Professor of Zoology/Curator of Herpetology in the Museum of Vertebrate Zoology. Preference will be given to individuals with teaching and research specialization in physiological ecology, behavior, or related areas of organismal biology, particularly as applied to reptiles. The successful candidate will teach courses in vertebrate biology including natural history, develop graduate teaching and research programs, and have curatorial responsibilities. Applicants should send a curriculum vitae, copies of publications, a detailed statement of teaching and research accomplishments and objective, and names and addresses of at least three references to: Chairman, Herpetology Search Committee, Department of Zoology, University of California, Berkeley, Ca. 94720. Review of applicants will begin 1 January 1978.

The University of California is an Equal Opportunity/Affirmative Action Employer. Women and minority candidates are encouraged to apply.

Either stock or custom made.

Need Reptile, Amphibian & Specimen Identification Tags?

Order them here and now.

Save time, money and patience. In that order. By ordering identification tags, just as you see them here, right now from Kimball Tag & Label. Use this page as your order form.

Non-soluble and waterproof inks • Special 10-pt. stock impervious to solvents • Alcohol and formalin proof • Pre-punched • Consecutively numbered* • Rolls of 2M • 1-week delivery • Custom tags take slightly longer but can be printed on *both* sides.

*Note: our stock tags are consecutively numbered but the starting number will vary for each shipment.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of Herpetological Review in 1967 (Corson Hirschfeld, Editor):

> "Herpetological Review incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the Review will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Now in its tenth year, Herpetological Review remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the Journal of Herpetology -- see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Authors are urged to write the editors before submitting feature-length articles. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles are desired. Submissions should be black-and-white, 8 X 10, glossy prints, and should be accompanied by a descriptive caption and exposure data. The name and address of the contributor should be taped or penciled on the back of each print. Please DO NOT send photographs before corresponding with the editors about them. Return of unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions can be supplied if desired. Contributors will receive ordering information prior to publication of their material. Herpetological Review will accept commercial advertising. Rates and copy information are available from the editors.

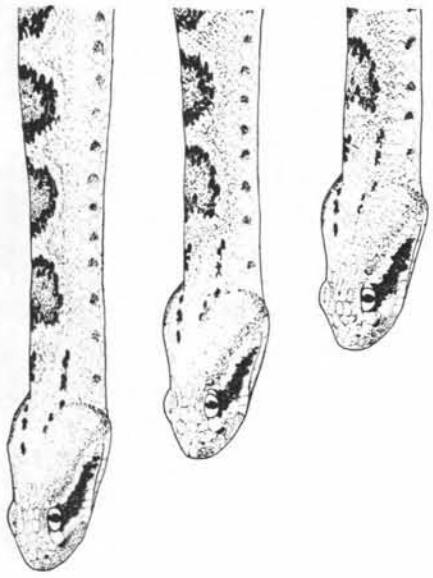
SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the Journal of Herpetology (four issues per year), Herpetological Review (four issues per year), Herpetological Circulars, and several Facsimile Reprints in Herpetology. Members may purchase other Society publications at reduced rates.



Annual Dues

Student Member	$ 8.00
Regular Member	10.00
Sustaining Member	15.00
Contributing Member	20.00
Institutional Subscription . . .	20.00

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of the SSAR. For information regarding SSAR membership, write to:

HERPETOLOGY AT THE UNIVERSITY OF CALIFORNIA-BERKELEY

Herpetological research and education at Berkeley date from the first decade of this century. William Ritter conducted life history studies of salamanders and sponsored such students as Loye Miller. When Joseph Grinnell founded the Museum of Vertebrate Zoology in 1908, that unit became the local center for studies of ecology and systematics. Grinnell was principally an ornithologist, but he conducted research on amphibian and reptilian distribution and sponsored a number of students. Tracy Storer, Charles Camp, Jean Linsdale, Henry Fitch, and Tom Rodgers were students who later served in a variety of staff and faculty positions at Berkeley. Camp's interests shifted from living to fossil lower vertebrates, and in time he became Professor of Paleontology and Director of the Museum of Paleontology on this campus.

David Wake, whose duties as Director of the Museum of Vertebrate Zoology keep him from using his microscope.

The Museum of Vertebrate Zoology continues to be the principal center of herpetological research at Berkeley. The collections now include about 150,000 catalogued specimens, with major emphasis on western North America, Mexico, and Central and South America. Robert Stebbins was the first permanent faculty curator of the herpetological collection, and following his appointment the level of research and teaching activity in herpetology increased greatly. A second faculty curator, David Wake, joined the University in 1969 and is now Director of the Museum. A third faculty member associated with the Museum is Marvalee Wake, Associate Research Morphologist. The Museum has a wide variety of special collections and research facilities, including a fully developed laboratory for biochemical genetics under the supervision of Curatorial Associate Richard Sage. A special feature of the Museum is a large, fully catalogued frozen tissue collection which is made available to qualified investigators. The Museum operates the Hastings Natural History Reservation, a 2,000 acre reserve with laboratories and residences located in the Upper Carmel Valley near Monterey and Salinas, California. John Davis, an ornithologist who also conducts studies of lizard ecology, is the resident in charge of the Reservation.

Robert Stebbins (wearing hat), Professor of Zoology and Curator in Herpetology, graduate student, Ted Pappenfuss, and Research Associate Nate Cohen barter with local collectors in Baja California for Bipes, the subject of Ted's doctoral thesis.

Affable Paul Licht must resort to intimidation to earn the respect of his students, Duncan MacKenzie, a comparative endocrinologist, Martin Feder, who recently completed his doctoral thesis on the physiological ecology of tropical salamanders, and postdoctoral student Antonella Gallo.

Robert Stebbins has conducted studies of the ecology, physiology, systematics and conservation of amphibians and reptiles. Currently, he is deeply involved in conservation efforts associated with off-road vehicle damage to the southwestern deserts. David Wake is studying the evolutionary biology of salamanders, with emphasis on comparative and functional morphology, systematics, and distributional ecology. Marvalee Wake emphasizes morphological studies of the reproductive system in lower vertebrates, and the evolutionary biology of caecilians. O.P.

Marvalee Wake, Associate Professor of Biology and Zoology and Associate Research Morphologist in the Museum, happily contemplates caecilians.

Pearson, retired Director of the Museum, maintains an active research program, including studies of the ecology of South American lizards. Paul Licht, Professor and Chairman of Zoology, is a physiological ecologist and comparative endocrinologist, currently involved in studies of the pituitary hormones of reptiles and amphibians. Other faculty members in Zoology who conduct research on amphibians and reptiles or sponsor students in these areas, or both, include Richard Eakin (comparative embryology, photoreceptor ultrastructure), Robert Colwell (community ecology), and Howard Bern (comparative endocrinology).

Faculty members in other departments who are actively involved in research on lower vertebrates and who sponsor students in certain aspects of herpetology include Allan Wilson in Biochemistry (anuran evolution), Vincent Sarich in Anthropology (lizard evolution), Joseph Gregory in Paleontology (lower vertebrate paleontology), E.R. Lewis in Electrical Engineering and Computer Sciences (structure of anuran inner ear), and Carl Nicoll in Physiology-Anatomy (endocrinology of prolactin).

Sam Sweet, who works with spring and cave salamanders of the Edwards Plateau, finds microscopes useful in telling dorsal from ventral sides of snakes. Sam will be Assistant Professor of Biological Sciences at the University of California, Santa Barbara, starting this fall.

Ray Huey, basking momentarily, will join the University of Washington this Fall as an Assistant Professor of Zoology.

There is an active post-doctoral program at Berkeley sponsored principally by the Miller Institute for Basic Research in Science. Miller Fellowships are two years in length and offer a generous stipend as well as research support. Ray Huey is a current Miller Fellow, and other recent fellows in this program include such herpetologists as George Gorman, Steve Arnold, and Al Bennett. Other current postdoctoral students in herpetology include Antonella Gallo and Ellen Daniel (both comparative endocrinology) and Craig Gundy (lizard photoreceptors).

Research Associate Anita Pearson applies ultrastructure techniques to the study of endocrine organs. Gloria Wurst studies developmental endocrinology and collaborates with David Wake in studies of evolutionary genetics of salamanders.

Curatorial Associate Gloria Wurst works with the Museum's herpetological collection, but the electrophoresis lab is her first love.

Since 1970 a number of students have been awarded Ph.D. degrees in some aspect of herpetology, including Kristin Berry, Charles Brown, Allan Brown, Dennis Bramble, Pille Bunnell, Bruce Bury, Susan Case, James Edwards, Eduardo Fuentes, Joseph Crim, James Lynch, Linda Maxson, Virginia Maiorana, Charles Muller, John Ruben, Judy Stamps, James Stewart, and Hing Wo Tsui.

Pedro Alberch, second year graduate student from Barcelona, is enthralled with x-rays of South American salamanders.

Graduate students who have just completed their degree work include Martin Feder, Steve Ruth (comparative lizard demography), Lynne Houck (reproductive biology of tropical salamanders), and Sam Sweet. Current graduate students include Pedro Alberch, Kay Yanev, Julie Feder (hybridization of Bufo), Tom Hetherington (salamander photoreception),

Kay Yanev has lost part of her head over her computer output. She is presently completing her doctoral thesis on genetic and morphological diversification of Batrachoseps.

Ted Papenfuss, Kristine Tollestrup, Duncan MacKenzie, Ron Marlow, John Cadle (salamander evolutionary genetics and snake systematics), Jim Hanken (genetic and morphological studies of Thorius), David Dobkin (lizard ecology), Bill Rainey (sea turtle evolution and biology), Jacques Gauthier (anguinomorph lizard paleontology, comparative anatomy and evolution). Undergraduates often are involved in various research projects, and currently Brad Shaffer (who will be a graduate student at the University of Chicago this fall) and Paul Elias, both working with Guatemalan salamander biology, are the most actively involved.

Curatorial Associate Dick Sage, on right, and gradute students Kristine Tollestrup and Ron Marlow are studying the Santa Cruz Long-toed Salamander. Their main interests are the evolutionary genetics of the Rana pipiens complex, ecological studies of Crotaphytus, and the biology of desert tortoises, respectively.

A CASE OF GONADAL ATROPHY IN LISSEMYS PUNCTATA PUNCTATA (BONNT.) (REPTILIA, TESTUDINES, TRIONYCHIDAE)

During our studies on gonadal cycles in some fresh water turtles, we captured a normal-appearing adult female Lissemys punctata punctata (Cat. No. JUBR-57, deposited in the Museum of the Department of Bio-Sciences, University of Jammu) on 2 March 1976 from a shallow pond near Ranbirsingh Para, Jammu (India). The turtle was measured, weighed and cut open (measurements and other data are provided in Table 1). Based on our observations of gonads in this species, this specimen's gonads presented an appearance entirely different from normal ovaries. The structures did not resemble normal testes either. The specimen was definitely a female. The literature available on gonadal abnormality in chelonians (Cagle, 1950; Hansen, 1943; Risley, 1941) makes no mention of the gonadal condition observed here.

The gonads, along with their ducts, were excised, measured and weighed (see Table 1). They were washed in physiological saline and fixed in dichromate-formalin-acetic acid fixative. A small piece of the fixed material from gonads and associated ducts was processed for sectioning and staining. Sections were cut at 7 micra, stained with Mallory's trichrome stain and microphotographed.

In all its external features, the turtle appeared a normal, mature female. The gonads, here considered "ovaries", occupied the normal position in the abdominal cavity and were whitish in color and spongy in consistency. These ovaries were lobulated with deep interlobular grooves and sharp marginal notches (Fig. 1). Normal ovaries in females of comparable measurements are yellowish in color and blistered in appearance due to numerous developing follicles of varying diameters. No follicles of any size were to be seen in these structures in our specimen. Moreover, in this specimen, these ovaries were considerably lighter in weight than normal ones.

The ducts associated with these ovaries, here considered "oviducts" (Fig. 1), were not fully developed, and were shorter and lighter in weight than normal oviducts in specimens of comparable size and weight. The anterior portion of each oviduct was attached to its gonad, which is also abnormal. Not only are normal oviducts free from the ovaries and open into the abdominal cavity anteriorly, but they also show an external demarcation into 4 regions, viz., the infundibulum, the tuber, the uterus and the vagina. Such an external differentiation in the oviducts of our specimen is completely lacking.

Histologically, the ovaries in the specimen were made up of numerous large and distended lacunae of varying shapes and sizes (Fig. 2). Most of these lacunae were partially filled with sparce, light-blue staining, non-cellular debris and a few darkly stained particulate in-

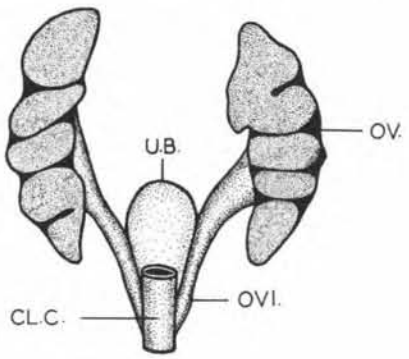

Figure 1. Lissemys punctata punctata, showing the general appearance of the abnormal ovary and the unusual connection between it and its oviduct. OV. ovary; OVI. oviduct; U.B. urinary bladder; and CL.C. cloacal chamber.

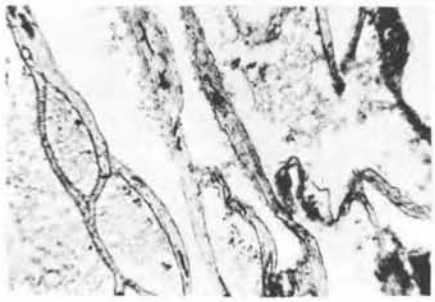

Figure 2. Cross section through the abnormal ovary, showing lacunae filled with a smear and boundary walls having blood cells and capillaries (X 120).

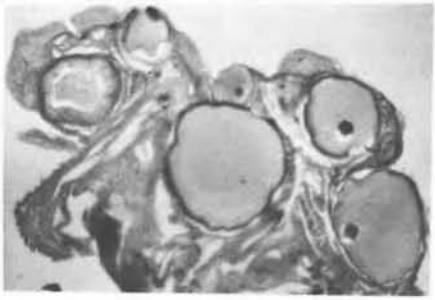

Figure 3. Cross section through normal ovary of L. punctata punctata showing oocytes at different stages of growth (X 50).

clusions. The boundary walls of the lacunae showed the presence of some globular transparent structures, of a non-cellular nature. Similar structures were also found within the lacunae. Large numbers of capillaries and free blood cells were, however, seen in the inter-lacunal filling. The normal histology of ovaries obtained during our study from individuals of comparable size and weight reveals the occurrence of oocytes at different stages of growth, a few corpora lutea and some atretic follicles (Fig. 3). As seen in transverse section, the oviducts resembled normal ones in their histological elements except for a low columnar epithelium on the lumenal side. Perhaps, the low height of the oviducal epithelium, particularly in the tuber portion, is indicative of the failure of production of the ovarian hormones responsible for preparing the oviducts for the reception of the eggs.

We feel these ovaries suffered total atrophy before producing any oocytes or eggs. Although it is presumptuous at present to attribute this type of total ovarian dysgenesis to any specific cause, a disturbed hormonal interplay as the chief factor in this case could not be ruled out.

ACKNOWLEDGMENTS

Authors are grateful to Professor Y.R. Malhotra, Head, Department of Bio-Sciences, University of Jammu, for facilitating our working in the department.

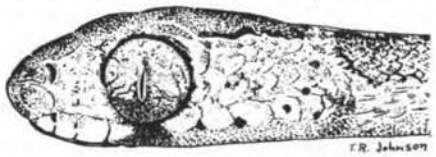
THE STATUS OF DRYMARCHON CORAIS COUPERI (HOLBROOK), THE EASTERN INDIGO SNAKE, IN THE SOUTHEASTERN UNITED STATES

In recent years, zoologists, naturalists, and others have expressed serious concern about the apparent decline or disappearance of Drymarchon corais couperi over much of its original range. This paper will evaluate the current status of this species in the southeastern Coastal Plain.

Drymarchon corais reaches the northernmost limits of its range in Effingham County, Georgia (Moulis, 1976). It inhabits xeric sandhill habitat over most of its range. Over much of the Coastal Plain, this form might be considered endemic to habitats which support populations of the tortoise, Gopherus polyphemus. Drymarchon utilizes the deep inclined burrows of these tortoises extensively for refuge and wintering. While D. c. couperi is typically associated with xeric habitats, it is sensitive to dessication, and may additionally rely upon these burrows to reduce moisture loss during dry periods (Bogert and Cowles, 1947).

Sandhill habitat typically includes longleaf pine (Pinus australis), turkey oak (Quercus laevis), and the wiregrasses (Aristida stricta and Sporobolus junceus). Each of these species may exist in greater or lesser density, and may be complemented by other pine and oak species. Other plants include saw palmetto (Serenoa repens), prickly pear cactus (Opuntia ompressa), lowbush blueberry (Vaccinium sp.), hawthorn (Crataegus sp.), and slender yucca (Yucca sp.). The soil is sandy or loamy, and is well-drained due to the porosity and elevation of the geological deposits.



Other vertebrate commensals of Gopherus burrows on a regular or incidental basis include the gopher frog (Rana areolata ssp. capito, sevosa, and aesopus), southern leopard frog (Rana utricularia), southern toad (Bufo terrestris), oak toad (Bufo quercicus), eastern glass lizard (Ophisaurus ventralis), ratsnakes (Elaphe sp.), eastern coachwhip (Masticophis f. flagellum), southern pine snake (Pituophis melanoleucus mugitus), eastern diamondback rattlesnake (Crotalus adamanteus), cottonmouth moccasin (Agkistrodon piscivorus ssp.), red fox (Vulpes fulva), coyote (Canis latrans), river otter (Lutra canadensis), opossum (Didelphis marsupialis), striped skunk (Sylvilagus floridanus), and numerous rodents. Thirty-two species of arthropods, including several endemics, have been found in tortoise burrows (Young and Goff, 1939).

This habitat is described as a fire-subclimax (Laessle, 1942). Periodic burning is essential to maintaining optimum wildlife carrying capacity and species diversity. Such burning occurred naturally in primeval times due to lightning or from accidental or deliberate burning by prehistoric man. Managed burning every 8-10 years removes accumulated leaf litter and keeps pine and oak size short and scrubby. Increased light and reduced leaf litter is conducive to wiregrass growth, which is an essential forage for Gopherus. Tortoise density within a given area is influenced by wiregrass prolificacy. In turn, it has been suggested that burrow-constructing vertebrates may contribute significantly to the carrying capacity of a habitat (Mount, 1963). The absence of periodic burning is increasingly evident in some portions of the Coastal Plain. Such areas have reduced wiregrass growth and a much lower tortoise density per acre.

The elevated, well-drained nature of the sand ridge habitat provides a prime site for construction, agricultural and forestry development, and livestock farming. Primitive and paved roads frequently transect these habitats. Physiographically, this habitat type has always occurred as disjunct segments randomly distributed over the Coastal Plain. There is no question that remaining natural sandhill habitats are rapidly declining, both in quality and in area. It is common to observe small tracts of this habitat directly adjacent to much larger areas of completely cleared farmland or pastureland, all part of the same sand ridge. It is obvious that such small tracts are merely remnants of much larger and extensive natural ridges. Loss of this habitat type in Florida has been estimated at roughly 5% per year (Ashton, pers. comm.). Comparable loss in Georgia is apparent. Encroachment of this type not only destroys the habitat for many species but also increases the likelihood of human encounter with the conspicuous indigo and other snake species.

The use of all terrain vehicles (ATV's) such as trail bikes and dune buggies is prevalent in many otherwise well-preserved sandhill areas. Indiscriminant use of these vehicles destroys wiregrass and other ground vegetation which is essential to soil stability. Basic forage for the tortoises is also reduced. Several such areas are reverting to a dune-like nature. Gopherus is unable to construct burrows in loose, drifting sand, resulting in disruption of the entire ecological community (Franz, pers. comm.).

The association of Crotalus adamanteus, the eastern diamondback rattlesnake, with Gopherus burrows, especially during the winter months, has brought about an additional and serious pressure on the entire tortoise community. Since the rattlesnakes frequently congregate in sand ridges to winter in the burrows, the practice of forcing these reptiles from the burrows by introducing varying amounts of gasoline through a plastic hose has become widespread. The advent and growing popularity of rattlesnake roundups and rodeos, centering around several small communities in southern Georgia, Florida, and Alabama, has significantly increased this pressure.

Many snake hunters are skilled at locating a snake in a burrow by listening through the hose. One half to six ounces of gasoline, ammonia, or some other noxious chemical is then introduced into the burrow if a rattlesnake is detected. Novice hunters may "fumigate" any hole in which a sound is heard. It has been estimated by Speake and Mount (1973) that fewer than 50% of the snakes subjected to "fumigation" in this manner actually leave the burrow. Personal observations and conversations with snake hunters would substantiate this estimate. In fact, a few hunters have discarded the technique due to its relative ineffectiveness.

A high mortality in colubrid snake species for this practice has been demonstrated (Speake and Mount, 1973). Of three specimens of Drymarchon corais couperi confined in tortoise burrows overnight, and exposed to two ounces of gasoline on the following morning, two died in twelve and fourteen days. The third was released after a twenty-four day observation period. All three snakes came to the mouth of the burrow within 3 to 35 minutes after the gasoline was introduced. That Drymarchon and other serpentine commensals of the tortoise community are incidentally or purposely gassed during snake hunts is certain. Fifteen specimens of D.c. couperi were collected by gassing from one large tortoise colony in Jeff Davis County, Georgia in early 1976. All were brought to the Claxton, Georgia rattlesnake roundup, where they were sold to a visiting Florida snake dealer (Moulis, pers. comm.). Personal investigation of six additional specimens from the same county, and at the same event, revealed that they had been excavated from two burrows in a different colony by another hunter. The latter specimens were sold singly to casual visitors to the roundup. All were in poor condition, with numerous skin lesions.

The eastern indigo snake has always been widely sought as a pet or for exhibition purposes due to the large size and docile nature of the species. It is the largest serpent species in North America, and specimens approaching eight feet in length were formerly common. It has been a highly commercialized species for many years. The preference of many specimens for a specific food item, which may be unavailable to the lay keeper, raises serious questions as to its propriety as a pet. In addition, the species is known to regularly harbor linguatulids, a primative arachnid parasite which is transmissible to man (Hunt, pers. comm.).

The effect of residual pesticides on Drymarchon populations has only begun to be evaluated. Three separate samples of body fat provided by the Atlanta Zoological Park to the Georgia Department of Agriculture for analysis yielded the following results:

Metabolites of chlordane

(PPM = parts per million)

#1 female

Heptachlor Epoxide	4.02 PPM
Trans Nonachlor	1.06 PPM
Octachlor Epoxide	0.87 PPM
Dieldrin	1.37 PPM

#2 female

Dieldrin	.08 PPM
Mirex	17.20 PPM

#3 male

Trans Nonachlor	.83 PPM
Octachlor Epoxide	.61 PPM
Dieldrin	5.6 PPM

#4 male

Octachlor epoxide	0.21 PPM
Trans Nonachlor	0.43 PPM
Mirex	0.55 PPM
PCB (arochlor 1260)	4.7 PPM
Heptachlor Epoxide	0.19 PPM
Dieldrin	1.0 PPM

#5 male

Octachlor Epoxide	2.39 PPM
Trans Nonachlor	2.42 PPM
PCB (arochlor 1260)	12.3 PPM
Heptachlor Epoxide	0.65 PPM
Dieldrin	13.3 PPM

Alarmingly high levels of these materials in initial samples indicate the need for extensive analysis.

The last record for D.c. couperi in Alabama was taken in Covington County in 1954 (Neill, 1954). This species was reportedly extirpated in Mississippi in the 1930's and 1940's (Mount and Speake, in press). Only one reference to the species in South Carolina has been located (Ditmars, 1939). No specific records are known. However, remnants of

suitable habitat occur in Jasper County, South Carolina, directly across the Savannah River from identical habitat in Effingham County, Georgia. Although extensive field examination has failed to yield specimens in the South Carolina locality, there remains a possibility of a population existing there.

It is appropriate to suggest that remaining viable and natural populations of this species occur only in Georgia and Florida.

In Georgia, D.c. couperi seems to prefer the Miocene and Plio-Pleistocene marine terrace sand deposits in the middle and lower Coastal Plain of the southeastern quadrant of the state. Only one verified record for this species in southwest Georgia is available (Seminole County, Ashton, pers. comm.). Due to the paucity of suitable habitat in the Dougherty Plain, one suspects this represents a northward extension of Florida panhandle populations, rather than a continuous range across southern Georgia. All records occur in association with xeric sandhill communities. There appears to be a strong preference for tortoise communities constructed on weathered river dunes which are adjacent to or near tupelo (Nyssa aquatica) or bald cypress (Taxodium distichum) swamps, river bottoms, or large tracts of pine flatwoods. Drymarchon appears to range into more mesic habitats during periods of moderate temperature and greater precipitation. Many food species are more abundant in these wetter habitats.

In Florida, Drymarchon remains intimately associated with the sandhill habitat north of Lake Okeechobee, although it is not uncommon to find wandering individuals in decidedly mesic situations. In southern Florida, the species is often common along canal banks, where it may enter the water when pursued, or attempt to escape into the numerous crab holes along the banks. I examined thirteen specimens from these habitats at several localities off Highway 1, near Florida City, Florida, in the late 1960's. Australian pine hammocks, which often comprise the highest terrain in the area, are also frequented by the species. Judging from the escape measures employed, the crab holes are analogous to tortoise burrows in more northerly populations as a place of refuge. A DOR specimen was taken in August, 1969 on Highway 27 in Taylor County, Florida, east of Perry. The habitat was mesic flatwoods. In October, 1970, a specimen was found in a xeric sandhill, 7 miles north of Niceville, Florida, in Okaloosa County.

Florida has protected the eastern indigo snake as a "threatened" species since 1971, due to habitat reduction, wanton killing, highway fatalities, and commercial collecting (Goodson, pers. comm.). In February, 1977, the Georgia Board of Natural Resources designated Drymarchon corais couperi as a "threatened" species under provisions of the Georgia Endangered Species Act of 1973. This step provides protection throughout its remaining range. Protection in Florida and Georgia prohibits the killing, capture, possession, or sale of this animal without permits from the state of origin.

The U.S. Department of Interior, Office of Endangered Species is currently evaluating the comprehensive status of this species. It is likely that it will receive federal protection within the immediate future. Such action would provide conclusive protection throughout the original range, making reintroduction into areas of extirpation possible. Federal matching funds may then become available to the states in question for management, research, and enforcement purposes.

Dr. Dan Speake, Alabama Cooperative Wildlife Research Unit, Auburn University, the Atlanta Zoological Park, and the Savannah Science Museum are assisting the Georgia Department of Natural Resources in specific areas of field and laboratory research, public education, and captive propagation. Dr. Speake is utilizing telemetry to determine home range, habitat preferences, and seasonal movement. A similar study, funded by the Zoological Society of Atlanta, will focus upon thermal preferences.

The potential for captive breeding of D.c. couperi is good. Many areas of prime habitat appear to have extremely low population densities, if indeed any individuals remain at all. Captive breeding from stock appropriate to the proposed release sites would eliminate potential egg predation and allow the monitoring of released hatchlings to obtain data on home range, seasonal range, growth in the wild, and other information. A formal recommendation has been made to the Georgia Department of Natural Resources regarding the development of General Coffee State Park, in Coffee County, Georgia as a natural history park. This park encompasses substantial sand ridge habitat and a dense tortoise population adjacent to the tupelo swamp backwater of Seventeen Mile Creek. Self guiding nature trails could be initiated to interpret the flora, fauna, and physiography of the habitat. Such limited development would increase public awareness and interest, would further justify the state's continued support of this little-used park, and would enable the establishment of an initial state sanctuary for Drymarchon recovery and study, without additional capital expenditures by the state (Lawler, 1976).

Essential to the protection and recovery of Drymarchon corais couperi is adequate protection for Gopherus polyphemus. Pituophis melanoleucus mugitus and Rana areolata sevosa, capito, and aesopus are other commensals of the Gopherus community thought to be declining in at least portions of their ranges. Securing Gopherus habitats and development of a practical recovery program for Drymarchon would directly benefit the entire sand ridge biotic community, and would provide "survival islands" for many species in the future.

There is a consensus among scientific investigators, naturalists, and even some commercial snake hunters, that Drymarchon has seriously declined in the southeast, and is a threatened, if not endangered species. Commercial collection, habitat loss, exposure to gasoline during rattlesnake roundups, wanton killing, and residual pesticides are continuing pressures of great concern. Commercial retail value has soared to from $75 to $250 per specimen. As the species becomes scarcer, the demand and value increases. Federal protection seems to be the only effective way of dealing with this factor. In addition, political considerations within Georgia may delay enforcement of laws prohibiting "fumigation" or other disturbance of tortoise burrows. Federal protection could address this problem on federal lands. It is doubtful that Georgia will have available funds to do more than provide de facto protection within the state. South Carolina has been apprised of the importance of "endangered" status in that state, due to old records there. The very real and vital necessity of acquiring and protecting suitable habitat would be greatly aided by federal protection and associated grants-in-aid to state endangered species programs.

Without positive action toward the full protection and recovery of Drymarchon corais couperi and its prime habitat, the future survival of this and allied species appears to be highly questionable.

OBSERVATIONS ON BREEDING MIGRATIONS OF AMBYSTOMA TEXANUM

In Kansas, Ambystoma texanum migrates to breeding sites after rains during late February or early March (Collins, 1974). This paper provides new information on various aspects of migration and reproduction in a Kansas population that I observed in 1974 and 1975.

Salamanders were collected from a one-mile stretch of blacktopped road (31st Street between Louisiana and Haskell Streets) in Lawrence, Douglas County, Kansas. Search of the road began soon after dusk on each day in which precipitation had occurred and for several days afterward from February through May. Salamanders were preserved and tagged within three hours of collection. Direction of travel, sex, and snout-vent length was recorded for each animal. In the laboratory, sizes of oviducts, ovarian eggs, opistonephric ducts, and testes were measured with an ocular micrometer or vernier calipers. Number of ovarian eggs were counted and stomach contents were examined. Statistical tests follow Sokal and Rohlf (1969).

Salamanders traveled to the low-lying fields of the Wakarusa River floodplain south of the road and then returned to the north side after breeding. The pattern of direction of travel in both years was an increasing percent of northerly directed salamanders as the season progressed (Table 1). The first appreciable rain of the year occurred on 6 March 1975 when 75 salamanders were collected traveling south. Successive collections showed an increasing percent traveling north. On a comparable date one year earlier, most salamanders were oriented north as was the case with successive collections. Salamanders had migrated south earlier as evidenced by eggs developed to yolk-plug stage found at the breeding site on 2 March. However, the road was searched on four previous occasions beginning on 12 February and no salamanders were seen. Collins (1974) found eggs in the same population as early as 25 January. No sexual differences were noted in timing or direction of travel.

	Date	n	% traveling north
1974	4 Mar	24	63
	28 Apr	17	82
	29 Apr	12	92
1975	6 Mar	75	0
	26 Mar	19	32
	7 Apr	19	74
	13 Apr	13	77

Table 1. Chronological changes in direction of travel.

Table 2 shows various statistics for pre- and post-reproductive animals. All males were mature judging from size of reproductive organs, swollen cloacas, and presence of spermatophores. Two females (SVL - 45, 46 mm) were judged immature based on undeveloped ovaries and small oviducts (0.20, 0.15 mm). Mean snout-vent length of 77 males was 74.0 $\pm$ 0.58 mm (range 60-85) whereas in 74 mature females it was 79.1 $\pm$ 0.53 (range 69-88). The difference in size is significant ($t = 6.48$; $P < 0.001$). Sex ratio was not significantly different from 1 : 1 ($X^2 = 0.06$; $P > 0.50$). Pre-ovulatory females had uniform eggs 1.4-1.7 mm in diameter. Number of ovarian eggs ($\bar{x}$ = 658 $\pm$ 24) ranged from 341-896 and was correlated with snout-vent length $\hat{Y} = -1282 + 24.1x$ ($P < 0.001$). Regression of sizes of ovi-

	n	Number traveling N or S		Percent with food in stomachs	Width of oviduct (mm)	Width of opistonephric duct (mm)	Testis area (mm)
FEMALES							
pre-ovulatory	38	1	37	18.4	2.5±0.62	--	--
post-ovulatory	35	31	4	40.0	0.9±0.03	--	--
MALES							
pre-reproductive	56	0	56	12.5	--	1.2±0.03	33.5±1.30
post-reproductive	19	19	0	36.8	--	0.6±0.04	20.7±1.12

Table 2. Comparison of various statistics between pre-reproductive and post-reproductive A. texanum. Reproductive status of males was determined a priori by direction of travel. Testes approximated a flat, ribbon shape. As an index of testis size, area was computed by multiplying length by greatest width for each testis. Oviducts were measured near the middle of their length.

ducts, opistonephric ducts, testes, and swelling of male cloacas occurred after reproduction. One post-ovulatory female traveling south on 13 April 1975 contained 58 eggs in the left oviduct; the right oviduct, measuring 1.4 mm in diameter, was empty. A significantly higher ($P < 0.05$; Sokal and Rohlf 1969, p. 607) percent of both post-reproductive males and females contained food in the stomach compared to pre-reproductive animals. Apparently, sexually active A. texanum feed little as is true for A. maculatum (Shoop, 1967). Earthworms were the most frequent food item, being found in 34 of 35 stomachs. One stomach contained a centipede and two other stomachs contained, in addition to earthworms, fragments of a beetle, a weevil, and a spider.

ACKNOWLEDGEMENTS

I thank Melissa Plummer for assistance in collecting salamanders. Joseph T. Collins commented on the manuscript. Sherry Davis kindly typed the manuscript.

Book Reviews

THIS BROKEN ARCHIPELAGO: CAPE COD AND THE ISLANDS, AMPHIBIANS AND REPTILES. By James D. Lazell, Jr., with photographs by Martin C. Michener, 1976. Demeter Press, Quadrangle/The New York Times Book Company, N.Y., N.Y. xi + 260 pp. $12.50.

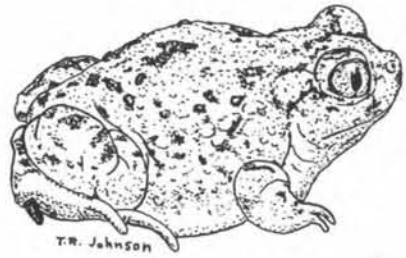
The 37 species of amphibians and reptiles known from Cape Cod and its associated islands are presented to the readers of this book with true affection by the author. This is not only a systematic treatment, but a chronology of the author's, and his friends', adventures as herpetologists in the field. The emphasis is on the living animals, where they occur and what they do. The outstanding feature throughout is Lazell's ability to develop a genuine fondness for the small, sometimes slimy, secretive, and mostly misunderstood members of these two vertebrate classes. The book is a first attempt, excepting Roger Conant's field guide, to assess the herpetology of this area. The text is easily read, often humorous, interesting, informative, and sometimes caustic in its attack on individuals, professional and amateur alike. His pointed comments refer primarily to field collecting for museum specimens and taxonomic considerations. One explanation for some rather heavy language may be the author's affiliation with the Massachusetts Audubon Society, but nowhere are his biases totally unfounded.

Chapters 1 and 2 discuss the land and the sea, respectively, describing in understandable detail the glacial origins of the area, the dynamic interactions of land, wind, ice and water. Terms such as knobs, terminal moraines, kettles, pamets and tombalos are so vividly defined that they would be easily remembered, even without the fine habitat photographs. These, and similar terms throughout the text, are also italicized for easy reference. Seral stages of vegetation, subclimaxes and ecotones are described for each island group to contrast the diversity of community types in the area. Of even greater importance, in Chapter 2, the all pervasive role of the sea in shaping the coastal land masses, and cyclicly controlling temperature and salinity, is described.

Chapters 3 through 7 describe the herpetofauna. Each chapter begins with a brief overview of the general origin, distribution and systematics of the order being introduced. In several individual species accounts problems of general biological interest concerning such varied topics as genetics, physiology, and zoogeography are presented. Examples include a discussion of DNA and the genetics of polymorphism in Plethodon cinereus, the peculiar distribution of Notophthalmus viridescens in this area and the hypothesis of a correlation of distribution and the salinity of breeding sites, the taxonomic question of recognizing Notophthalmus instead of Triturus as the real generic name, the nagging question of where Hyla crucifer goes during the "off" season, and why do many herpetologists exhibit what Dr. Lazell terms "ignorance" of the literature concerning systematic revisions? Explaining to a non-biologist the role of DNA in the genetic polymorphisms of Plethodon required considerable insight and writing talent. Lazell does a fair job in about 3 pages. Those who would recognize the simplified, and basically erroneous, statement that "a gene that doesn't work is called recessive" may criticize it. But, in his context we could do much worse in explaining that gene's contract to a dominant one. I do take exception to his view of introgression as "hybrids...so well adapted to new conditions that they out breed either parental stock" (p. 108). His statement, in my opinion, refers to a hybrid swarm. Introgression more properly refers to backcrossing of the F1's by either parental populations. As to "ignorance," Dr. Lazell rightly points out the problems, but does little to indicate solutions (quite unexpected from a Massachusetts Audubon member). If one recognizes how immense was the genus (in this case Natrix), and how variable, then one must admit that a proper definition requires a monographic study of no small effort. With reference to Ed Malnate's study of the genus Natrix, such an effort has split out Natrix from three other genera, and most have accepted the split in principal (including McDowell). Douglas Rossman, an extremely thorough worker, has now separated New World from Old World Natrix, the former designated Nerodia and the latter Natrix. The original Natrix complex, thus pared down, might now be ready for a reexamination of Nerodia-Natrix-Thamnophis affinities. Classifications are slow to change--and in many cases should be. Lumping often obscures problems. Witness the long standing myth of the singular, wide ranging Rana pipiens, or the Natrix sipedon-fasciata complex as a single species group. Surely the lumping of Thamnophis with Nerodia requires more than Lazell's "footnote." The irony of the argument is that while Thamnophis may be Natrix they may not at all be Nerodia!

One recurring theme throughout the book concerns the author's almost fanatic aversion to collecting museum specimens, and the seemingly

continuous instruction against displacing individuals from their natural habitats. Unfortunately, in making his point Lazell must admit to paucities of data, or record sized specimens that were not preserved due to this philosophy. I am sure Lazell realizes the importance of museum specimens, as individual records or as series. In several places he does suggest the collection of a voucher specimen. Personally, I believe his aversion to collecting museum specimens is a ploy to down beat the tendency of the young, exuberant, and inexperienced to go hog wild! Similarly, for the several reasons and examples Lazell so clearly presents, no one should attempt displacement of a species from its natural habitat.



Chapter 8 concerns zoogeography of the area based on the herpetofauna. As stated, it is true that we need more in-depth field studies and perhaps less theorizing. However it is unfair, unjustified, and downright wrong to single out MacArthur and Wilson's theory of island biogeography as "worthless." The very fact that Lazell devotes a chapter to the subject and attempts new interpretations, is justification enough for the worth of their efforts.

I enjoyed this book so much that I found little more to criticize that would not be considered trite or just plain philosophical argument. A few typographical, grammatical and illustrational errors are listed here mainly to indicate I read the book thoroughly! "Cape Page" should be Cape Poge in the figure on p. 8; "tell" should be tells (p. 110, line 12); "American toads...breed later" should be breed earlier on p. 111, line 15; "occurs" should be occur (p. 111, line 31); there is an apparent smudge on the right arrow of the figure on p. 112; "impotrant" should be important on p. 140, line 2; the photograph on page 190 is upside down; shading of the figure on p. 199 obliterates locality data; "Opmeodrys" should be Opheodrys in the figure legend on p. 212; "stock" should be stocky on p. 248, line 2.

Most of Martin Michener's photographs are truly outstanding, particularly the frogs and toads, the smaller turtles, and the larger snakes. A compliment to his talents is in reference to his photograph of Natrix s. sirtalis on p. 221, which is every bit as good as the one taken by the late Isabelle Hunt Conant. Michener presents good suggestions for photographing reptiles and amphibians in the last chapter.

This book will be valuable to different groups of people. To the amateur herpetologist and the interested layman, the text will be readable, providing details that took me years to learn in the field. For the high school biology teacher there are many suggestions and examples for the use of laboratory experiments in a natural setting. Professional herpetologists will find interesting hypotheses to test, fine distributional maps, some discussion of geographic variation (however, there are no tables or figures depicting individual variation), and some soul searching arguments which I am sure Lazell will be happy to debate.

TERRY D. SCHWANER, Division of Herpetology, Museum of Natural History, The University of Kansas, Lawrence, Kansas 66045.

LISTE DER REZENTEN AMPHIBIEN UND REPTILIEN. HYLIDAE, CENTROLENIDAE, PSEUDIDAE. By William E. Duellman, 1977. Das Tierreich, Lief. 95, xix + 225 p. 280 DM (about $117).

Checklists can be among the most useful documents in taxonomic biology. At their lowest level of development--as simple, unadorned lists of species on a taxonomic or geographic basis--their utility is limited and they are likely to age rapidly. But when a checklist is carefully produced to cover one or more large groups, includes extensive synonymies, gives type-localities, cites type-specimens for all species-group taxa, and is thoroughly indexed, then such a checklist is assured a permanent place in the active literature. This is such a work, and the author deserves the plaudits of his colleagues.

This checklist includes as valid taxa (by Duellman's count), 36 genera and 544 species of Hylidae, 2 genera and 55 species of Centrolenidae, and 2 genera and 4 species of Pseudidae. I made no effort to count the number of junior synonyms cited, but the index comprises 21 pages of small print--from acheta to zweifeli. The literature base for the checklist runs through 1974. References are for the most part contained within the synonymies and are given in the customary but lamentable abbreviated mode of citation, omitting titles. The entry for each taxon includes "the most recent publication on the taxon" (presumably the most recent publication of taxonomic significance or utility). If this reference does not appear in the synonymy, there is a separate entry in a terminal bibliography where the much more useful full citation style is employed.

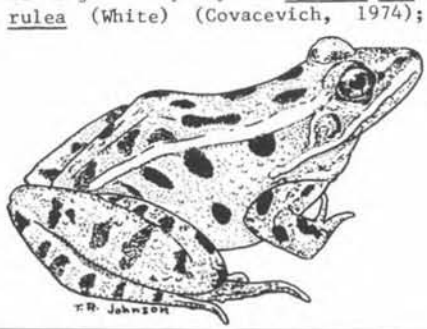
Having expressed my admiration for this publication, I must fulfill the critic's obligation of looking at the other side of the coin. One area where this checklist may create problems for taxonomists is in its listing of "new combinations." Duellman (p. ix) states that "taxonomic changes normally should not be made in a checklist," and I agree completely. However, he finds it necessary to make some changes "for the sake of nomenclatural consistency and stability." Again, I agree that in some instances this may be appropriate; the alternative may mean cluttering the literature with numerous short notes. Some of the new combinations are really not new, however. Duellman specifies ten species of Centrolenella as new combinations (only nine appear in a list on p. ix, but a tenth, C. petropolitana, is in the body of the text), but nine of these species had already been listed under Centrolenella without being indicated as new combinations, by Gorham (1974).

Duellman (p. x) states "New combinations of names listed by Gorham (1974), none of which is supported by evidence, are not included." The difference in evidence seems to lie in Duellman's citing references some of which presumably were available to Gorham but were not cited in his less elaborate format. It would have been better had Gorham indicated new combinations where he created them, but in any event, Duellman's cavalier treatment of Gorham's useful list should not deter taxonomists from determining where particular name combinations were first used.

Tyler's (1971) resurrection of the genus Litoria for frogs of the Australian region formerly placed in Hyla raised questions as to the use of some names that, as secondary homonyms, could not be used in Hyla. One instance is Pelodytes affinis Gray, a name preoccupied by Hyla affinis Spix prior to the revival of Litoria. Nieden (1923) rejected affinis Gray and provided the substitute name Hyla tornieri. Later authors (Loveridge, 1935; Copland, 1957; Moore, 1961; Tyler, 1971) did not recognize tornieri as a valid species, but Cogger (1975), in a work published after Duellman's checklist went to press, revived tornieri (in the new combination of Litoria tornieri) and made diagnostic comparisons. Duellman too listed the species as valid, but under the new combination Litoria affini (Gray), and gave no indication of why specific recognition is warranted. The revival of affinis was improper, and according to Article 59 of the In-

ternational Code (1974 amendment), a junior secondary homonym rejected before 1961 (as Nieden did with affinis) is permanently rejected. Litoria tornieri evidently is the correct name. As an aside, I note that in the synonymy of Litoria affinis, Duellman (p. 114) lists "Hyla latopalmata latopalmata--Copland (partim)," but Copland (1957: 89) placed affinis and tornieri in the synonymy of Hyla lesueurii.

What seems to me an unwarranted revival of a senior synonym is Duellman's use of Litoria punctata Dumeril for the species known for decades as Hyla cyclorhynchus Boulenger and more recently as Litoria cyclorhynchus. The name punctata does not appear to have been used in more than 100 years, was identified with a known species relatively recently (Moore, 1961:319-320), and has an erroneous type-locality. The name would appear to be an excellent candidate for suppression as an "unused senior synonym" (International Code of Zoological Nomenclature Article 79b), and Duellman would have been well advised to "maintain existing usage...and refer the case to the Commission for a decision under the plenary powers" (op. cit., Article 23 a-b).



With regard to whether the author of a checklist accepts the most recently published assessment of the taxonomic status of a given form, he is in a difficult position--likely to be damned if he does and damned if he does not. A case in point is Duellman's acceptance of numerous synonymizations or changes from species to subspecies level recommended by Lutz (1973). In reviewing Lutz's book Duellman (1974) was properly critical of changes instituted therein, many of them made with little or no new evidence. I think he would have been justified in rejecting such changes in nomenclature pending more complete study. A stronger case could be made for rejecting Lutz's taxonomy than for sweeping Gorham's new combinations under the rug. In another instance, what seems to be good evidence for restoring species rank to Hyla arborea savignyi was rejected or overlooked (Schneider, 1974), and in the same species group, the decision of Bannikov, Darevsky and Rustamov (1971) to recognize Hyla japonica as a species rather than a subspecies of H. arborea should have been considered.

The area of geographic distribution is one in which some explanatory notes would be helpful. One assumes that in the absence of indication to the contrary, distributional information is summarized from the literature. But what appears to be previously unpublished information is not so identified and, hence, undocumented. An example is the range "Mountains of northeastern Venezuela and Tobago" given for Centrolenella orientalis (p. 192). The inclusion of Tobago in the range of a species known previously only from a single specimen from a montane, mainland locality 370 kilometers away should be documented.

There is a refinement that I stongly urge on future compilers of such extensive checklists as this one. That is to set aside a separate section, thoroughly indexed for species originally described within the major group covered by the checklist but since transferred to a group outside the scope of the list in hand. Presumably the compiler of a checklist will have encountered such names and will have had to decide on their disposition. Thus, little extra work is called for, and the utility of the checklist will be significantly increased.

Consider, for example, the plight of one who might wish to determine the current status of Hyla chica Noble. The logical place to look would be in a checklist of the Hylidae, but since the name was subsequently identified as a junior synonym of an Eleutherodactylus, it has no place in the hylid list. Working back through the Zoological Record, one would eventually find reference to the synonymization in the volume for 1952. Another example is Hyla chimboe Fowler, which is more of a problem because it appears in Gorham's list (1974) in this original form. Unless the reader happened upon a recent paper by Lynch (1976), he would have no way of knowing that chimboe too is an Eleutherodactylus.

Attention needs to be directed to several items so that users of the checklist who so wish may annotate their copies; I include no literature later than the closing date for the checklist, 1974: Hyla kanaima Goin and Woodley (1965) and Hyla microterodisca Werner (1921) were omitted (evidently the latter is a junior synonym of Osteopilus septentrionalis (A. Schwartz and R. Crombie, pers. commun.); Phyllocytes auratus (Boulenger) is not a new combination as indicated on pp. ix and 157, but was first used by Bokermann (1968); Litoria irrorata (de Vis), listed as a valid species, is a junior synonym of Litoria caerulea (White) (Covacevich, 1974); Gastrotheca riobambae is not in the systematic index (p. xii); the specific name of Hyla chrysoscelis is misspelled throughout the text and index ("chrysocelis").

A great accumulation of data such as appears in this checklist can lead one to statistical doodling. I restrained myself to just one such operation: Duellman lists 603 valid species of Hylidae, Centrolenidae and Pseudidae. Of these, 264 (44%) were described by persons who lived at least into the closing year (1974) of the checklist. Aside from saying something about the longevity of herpetologists, this is an indication of the activity in the field of herpetological systematics.

In addition to the general excellence of the text, this is a physically well made publication. The paper appears substantial, the binding is good and the complex job of printing was carried out with few errors apparent to me. But at what a price! Even in a time when $40 technical books are commonplace, this volume stands out at about $0.50 per page. Future compilers of similar checklists should give serious throught to seeking out alternative means and places of publication.

AUSTRALIAN FROGS; HOW THEY STRIVE, THRIVE, AND STAY ALIVE

(Frogs, 1976, Collins Ltd., Sydney, 256 pp.; obtainable in the U.S.A. from Taplinger Publishing Company, 200 Park Avenue South, New York, New York 10003 for $17.50).

In recent years the parturition rate of popular and semi-popular books on amphibians and/or reptiles has been so great that it seems as though the attainment of the carrying capacity of the herpetological community should be imminent. In a packed community a newcomer is likely to survive only if it fills an unoccupied niche. Such is the case of "Frogs," a delightful new book in The Australian Naturalist Library, written by Michael J. Tyler of the University of Adelaide, Australia.

In the preface Tyler tells us: "There are really two major deficiencies in this literary void [publications for naturalists on Australian and New Guinean frogs): firstly a book providing information about the lives of frogs, enabling them to be appreciated as living animals and, secondly, one designed as a field guide for identification. These two objectives are quite different, and my book is concerned only with the first one, which is just how frogs strive, thrive, and stay alive." He has succeeded admirably. "Frogs" is a book about the biology of frogs based primarily upon examples from Australia and New Guinea but with relevant comparative information about species elsewhere in the world.

In a well-organized manner, the reader is presented with 18 chapters beginning with an introduction encompassing basic internal and external structure, distribution, Australian fossils, and a lucid, candid discussion of taxonomy. The latter should be required reading for all biologists. Following are four chapters, each dealing with one of the four families of native Australo-Papuan frogs: Hylidae, Leptodactylidae, Microhylidae, and Ranidae. The sixth chapter deals with the introduced toad, Bufo marinus. Chapters 7 through 16 are concerned with "how frogs strive, thrive, and stay alive," including reproduction, diet and feeding habits, obtaining water and avoiding heat, breathing, communicating by sound, facing enemies, parasites, dispersal, geographic distribution, and frogs and man. Another chapter provides an informative account of the history of herpetology (principally frogs) in Australia. The final chapter on the study of frogs includes commentaries on identification, collecting, maintaining living frogs and tadpoles, techniques of killing and preservation, and herpetological literature. The book concludes with an appendix mostly devoted to lists of the species known from each state in Australia, an extensive list of references organized by chapters, and an index. The illustrations, although not plentiful, are of excellent quality. Thirty-four text figures illustrate principally morphological features. The four black and white and 16 colored plates are excellent; most of these are photographs, and among them are the best illustrations of Australian frogs ever published.

Although the book is directed to Australian naturalists, it far surpasses its intended goal. Tyler writes lucidly and obviously is knowledgeable and enthusiastic about his subject. He whets the reader's appetite with fascinating narratives. He engenders an overwhelming desire to get into the field so as to observe frogs and seek answers to the many intriguing questions posed by the author while he skillfully leads his readers through the maze of information about the biology of Australo-Papuan frogs.

For example, the chapter on reproduction is introduced thusly: "Frogs vary in just about every detail of their reproductive behaviour and the subsequent pattern of development of the young. It isn't just a question of species choosing to be different for the sake of it. Rather the variation is a mirror of the environmental difficulties that have been overcome, and demonstrates a wide variety of success stories."

Tyler represents a fine blend of an astute field naturalist and an accomplished scholarly researcher. His compassion for his predecessors is well expressed in a passage in the chapter on herpetology in Australia: "In reading some of the studies of modern zoologists who have needed to re-examine specimens in some of the collections that were made, it is commonplace to detect a sense of frustration, irritation, and even ridicule at what, by modern standards, are interpreted to be errors of description, resulting from slipshod work. This veiled criticism is unfair, for the only way of assessing early contributions is to appreciate the quality of the techniques of study in vogue in those times, the great difficulty of communication between herpetologists, the absence of specialist journals, the enormous array of new animals demanding attention and concepts of species." How often we forget.

Australia has had many unfortunate intentional introductions of animals. Tyler provides a fascinating account of the history of Bufo marinus in Australia since its introduction in 1935. He takes cognizance of the social and economic reasons for the introduction of the toads, discussing the biological and commercial problems resulting from their population explosion and dispersal, and suggests methods of control. Tyler's approach to conservation measures contained in the chapter on frogs and man embraces a philosophy of the greatest good of all--protection of all species on special reserves, strict regulations on rare species, freedom for amateur and professional alike to utilize and study other species, and limited commercial exploitation of some common species.

Book reviewers are supposed to be highly critical, pointing out errors in the information content, the conceptual framework, the organization, the writing, and the layout of the book. In the case of Tyler's "Frogs" I have nothing but praise, except that I would have chosen a different colored binding.

American writers have been provided with a challenge, for no comparable book has been written on American frogs. With the reading of Tyler's book my enthusiasm for visiting Australia and observing its frog fauna has increased by several factors; probably I shall not be able to await a hoped for companion volume--a field guide.

WILLIAM E. DUELLMAN, Museum of Natural History and Department of Systematics and Ecology, University of Kansas, Lawrence, Kansas 66045.

Geographic Distribution

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same. The standard format for a geographic distribution record is:

Scientific name (common name) as it appears in Conant (1956, 1975) or Stebbins (1966). Locality (use metric for distances). Date and collector(s). Identified or verified by. Place of deposition and catalogue number. Comments. Citation. Submitted by (give name and address).

Please submit new geographic distribution records in the standard format only to Joseph C. Mitchell, Graduate Program in Ecology, University of Tennessee, Knoxville, Tennessee 37916. Short manuscripts are acceptable when data cannot be adequately presented in the standard format.

Recommended citation for new geographic distribution records appearing in Herpetological Review is: Jones, J. 1977. Geographic distribution: Rana pipiens. SSAR Herp. Review 8(1): 1.

SALIENTIA

RANA PALUSTRIS (Pickerel Frog). USA. ARKANSAS: Union Co: 10.3 km S Smackover. 7 June 1974. H.W. Robison. Southern Arkansas University uncataloged. Ouachita Co: Camden city limits at U.S. Hwy. 7, Ouachita River. 25 August 1974. L.D. Blalock. New county records extend known range within the state ca. 190 km S of nearest records in Monroe County and 83 km SE of a record in Polk County. Previous records are from extreme west, north and north central Arkansas (Dowling, 1956, Occ. Paps. Univ. Ark. Mus., 19: 18; Black and Dellinger, 1938, Occ. Paps. Univ. Ark. Mus., 2: 22).

Submitted by HENRY W. ROBISON, Dept. of Biological Sciences, Southern Arkansas University, Magnolia, Arkansas 71753. ●

SAURIA

ANOLIS SAGREI SAGREI (Cuban Brown Anole). USA. FLORIDA: Glades Co: Fisheating Creek Campground along banks of Fisheating Creek, 1 km S Palmdale off US 27. 25 March 1976. C.M. Corwin, et al. Verified by James N. Layne, Archbold Biological Station. Univ. South Alabama Nat. Hist. Mus. 2216-2217. This locality represents an extension of ca. 80 km NW and 160 km SE of Palm Beach County, and Tampa-St. Petersburg populations, respectively (King and Krakauer, 1966, Quart. J. Fla. Acad. Sci., 29: 144-154). Male and female specimens were collected, indicating a breeding colony is probably established in the area.

TESTUDINES

CHRYSEMYS NELSONI (Red-bellied Turtle). USA. FLORIDA: Baker Co: Osceola National Forest. Middle Prong, Little St. Mary's River, 7.3 km SW Taylor. 29 April 1977. Seined by C.R. Smith, W. Lippincott, and A. Powers. Verified by W. Auffenberg, Florida State Museum. FSM/UF 39066. First record for the county, and extends the range into the St. Mary's River drainage, approximately 65 km N of previously recorded localities (Carr and Crenshaw. 1957. Bull. Florida St. Mus., Biol. Sci. 2: 25-42).

Submitted by ARNOLD POWERS, c/o Department of Herpetology, Florida State Museum, University of Florida, Gainesville, Florida 32611 and C.R. SMITH, National Fish and Wildlife Lab, Gainesville, Florida 32601. ●

GRAPTEMYS GEOGRAPHICA (Map Turtle). USA. NEW YORK: Dutchess Co: Hyde Park. 1972. Donald C. Buso. Collection of Donald C. Buso. Rhinecliff. 28 July 1972. Nesting female marked and released by Erik Kiviat and Robert L. Bard. Hyde Park. 23 June to 16 July 1973. Six fresh nests. 27 August 1973. Nest with hatchlings emerging. (Seven clutches, 10-18 eggs, $\bar{x} = 15.1$). Donald C. Buso. Cornell University, R9726-9732. Staatsburg. 26 June 1975. Two nests (1 with 14 eggs, not fresh). Erik Kiviat. Bard College Field Station, uncataloged. All data from fresh-tidal Hudson River. Nearest published range margins (Conant, 1975, A Field Guide to Reptiles and Amphibians of Eastern and Central North America, Houghton Mifflin Co., Boston) are ca. 165 km N at Lake Champlain, and ca. 165 km W near Binghamton. The Hudson-Champlain canal (1820) may have been the dispersal route. Unverified reports suggest Hudson River range extends S to Poughkeepsie and N to Athens from localities reported here.

LAMPROPELTIS MEXICANA MEXICANA (Mexican Kingsnake). MEXICO. ZACATECAS: 2.74 km S Transcoso. 13 July 1964. E.A. Liner and H.A. Dundee. E.A. Liner private collection, EAL 1170. First record for this species from the state of Zacatecas.

Submitted by ERNEST A. LINER, 310 Malibu Blvd., Houma, Louisiana 70360 and HAROLD A. DUNDEE, Department of Biology, Tulane University, New Orleans, Louisiana 70118. ●

TANTILLA NIGRICEPS FUMICEPS (Texas Black-headed Snake). MEXICO. TAMAULIPAS: 16.3 km SW Reynosa on Mexico Hwy. 40. 3 July 1964. E.A. Liner and H.A. Dundee. EAL 992. This is the second record and third specimen from Mexico; all are from Tamaulipas. This record extends the range ca. 88.7 km due east on the first known locality, Mier, reported by Smith (1938, Copeia, 3: 150).

Submitted by ERNEST A. LINER, 310 Malibou B.vd., Houma, Louisiana 70360 and HAROLD A. DUNDEE, Department of Biology, Tulane University, New Orleans, Louisiana 70118. ●

HERPETOLOGICAL RECORDS FROM ILLINOIS

The following range extension and county records are reported for Illinois reptiles and amphibians.

COUNTY RECORDS. Caudata: Ambystoma texanum (Small-mouthed salamander). Effingham Co: jct. U.S. Hwy. 40 and Ill. Hwys. 32-32. 21 March 1975. J.K. Tucker. J.K. Tucker collection, JKT 67. Testudines: Pseudemys scripta elegans (Red eared turtle). Effingham Co: Lake Sara. 27 Sept. 1974. JKT 68. McLean Co. Lake Bloomington at jct. with Money Creek. 15 May 1969. Identified and released by J.K. Tucker. Sternotherus odoratus (Stinkpot). McLean Co: Lake Bloomington. 25 April 1970. T. Belander. Verified by J.K. Tucker. Illinois State Univ. Mus. #1767. Serpentes: Lampropeltis c. calligaster (Prairie kingsnake). Peoria Co: 1.6 km S Kickapoo. June 1963. Identified and released by D. Moll.

RANGE EXTENSION. Serpentes: Lampropeltis c. calligaster (Prairie kingsnake). Fulton Co: 1.6 km S Marietta. 19 April 1974. Identified and released by G.L. Paukstis and J.K. Tucker. Extends range 42 km NW and 59 km N of nearest records (Smith, 1961, Illinois Nat. Hist. Surv. Bull. 28(1): 1-298).

Submitted by DON MOLL, GARY L. PAUKSTIS and JOHN K. TUCKER, Department of Biological Sciences, Illinois State University, Normal, Illinois 61761. ●

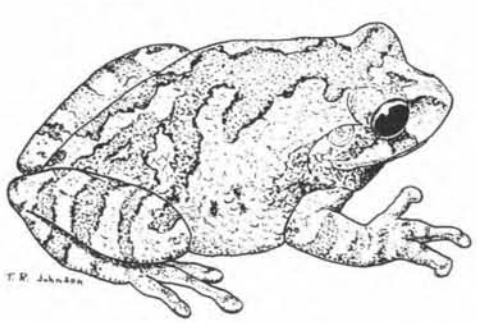
MUHLENBERG GROUP SPONSORS ESHL MEET

The Muhlenberg Group (TMG) of Augusta, New Jersey will be sponsoring the Fall 1977 Eastern Seaboard Herpetological League (ESHL) meeting. The meeting will take place on Oct. 8, from 12:30 to 7:00 p.m., and will be held at the Plains Community House, Plains Road, in Augusta. Subjects ranging from the bog turtle to sea snakes, to the conservation of amphibians and reptiles will be discussed. The following organizations are members of ESHL: N.Y. Herp. Soc., Conn. Herp. Soc., Mass. Herp. Soc., Philadelphia Herp. Soc., Md. Herp. Soc., Ga. Herp. Soc., Fla. Herp. Soc., Assoc. for the Cons. of Turtles and Tortoises, Inc., No. Ohio Herp. Soc., No. N. J. Herp. Soc., and TMG).



According to Mr. Tom J. Bloomer, Coordinator of TMG, the organization is in the process of printing the first in a series of field studies on members of the turtle genus Clemmys. The Bog Turtle...A Natural History is now available from TMG for 50¢ a copy plus 24¢ postage. The remainder of the natural history studies will be printed in the near future, and the accounts will be combined into a hard cover book in 1978.

Another project of TMG is the preservation of known habitats of Clemmys muhlenbergi. One area is a 100 acre bogland which must first be purchased at a cost of $300,000, and then the land will be turned over to the state of New Jersey as a bog turtle preserve. CONTRIBUTIONS FOR THIS PROJECT WILL BE WARMLY WELCOMED. Please make checks payable to: TMG Bog Turtle Fund.

The Group is also currently doing studies on other members of the genus Clemmys, on the northern pine snake, and on the Blanding's turtle.

To send contributions, or for more information, write to:

REGIONAL HERPETOLOGICAL SOCIETIES

The SSAR, through the efforts of the Liaison Committee, is attempting to establish a much closer relationship with regional herpetological societies. In order to accomplish that end, questionnaires were sent to all of the societies for the purpose of compiling a current list and to gain some input as to how SSAR might be of greater assistance to regional societies.

The Committee members, Stanley Dyrkacz, Tom Johnson, Gopher Kuntz, Michael Long and Malvin Skaroff, prepared questionnaires which covered the following topics: status of the society, heirarchy of the organization, membership, publications, frequency of meetings, and other pertinent information. The response was less than over-whelming and the list reflects the amount of information that was returned. The status of many societies could not be determined so any corrections or additions would be welcome. Please send all information to:

James B. Murphy, Chairperson
SSAR Liaison Committee
621 E. Clarendon Drive
Dallas Zoo
Dallas, Texas 75203

A revised list of societies will be published each year by the SSAR.

News Notes

AN OPEN LETTER ON AGAMID LIZARDS

As most museum curators already know, my doctoral thesis concerns the systematics of the lizard family Agamidae. During the course of my research, I have developed working correspondences with other herpetologists also studying various agamid taxonomic problems. In order to prevent duplication of effort and results by other persons, I shall summarize below which taxa are presently under study and by whom.

For my doctoral thesis, the monotypic genera or genera with only a handfull of species will be adequately treated. These genera include: Acanthosaura, Aphaniotis, Brachysaura, Ceratophora, Chelosania, Cophotis, Dendragama, Hydrosaurus, Lophocalotes, Lyriocephalus, Moloch, Oriocalotes, Otocryptis, Physignathus, Psammophilus, Ptyctolaemus, Salea, Sitana, and Xenagama. Leiolepis and Phoxophrys have already been revised in recent years by Gunther Peters and Robert Inger respectively.

I am also preparing revisions of the species of the larger genera Gonocephalus and Uromastyx, and of the sub-genus Pseudocalotes within the unwieldly genus Calotes. The "amphibolurine" radiation of agamids in Australia, including Amphibolurus, Caimanops, Chlamydosaurus, Diporiphora, Lophognathus, and Tympanocryptis, is being studied by Geoffrey Witten and other students of Harold Cogger in Sydney. The difficult genus Phrynocephalus is being independently studied by Gunther Peters in Berlin and Ronald Whiteman at the University of California at Fullerton.

The polyphyletic assemblage Agama is finally receiving long overdue attention. The sub-genus Stellio, the whorled-tail forms, is being revised by Gunther Peters. The Agama hispida species complex in southern Africa is being revised by G.R. McLachlan at Cape Town. Benedetto Lanza of Florence has completed a review of all Agama species, including several rare endemics, of Somalia. Dirk Kreulen of Holland is reviewing the Agama agama-lionotus-planiceps complex in the rift region of East Africa. Wolfgang Bohme and I are studying the relationships of several Agama species of the Sudanese vegetational belt of northern Africa.

Four diverse agamid genera are thus available for revision: Japalura, Draco, Calotes (excluding the sub-genus Pseudocalotes), and the sub-genus Trapelus, removed from Agama. This latter taxon includes the following species and many synonymous names: agilis, blanfordi, isolepis, sanguinolenta, savignyi, jayakari, flavimaculata, tournevillei, fieldi, kirmanensis, mutabilis, pallids, agnetae, ruderata, megalonyx, rubrigularis. Willi Hennig, famous for his original contributions to cladistics, revised Draco in 1936 for his doctoral thesis. He recognized 16 species and 21 subspecies, not including the nominate forms. However, given the analagous island archipelago radiation of Anolis, I would strongly recommend a reexamination of Draco.

I hope that the above information will be of use to other herpetologists. I will gladly share my voluminous notes concerning the whereabouts of type specimens and my lists of species available for study in all museums in America and Europe. I would also appreciate being informed of other agamid studies, in the present and the future, in order to continue a cooperative effort in the study of agamid lizards.

SCOTT MOODY, Museum of Zoology, University of Michigan, Ann Arbor, Michigan 48109 USA.

TORTOISE DATA DESIRED

Persons having data on care in captivity, field observations and/or photographs of rare species of tortoises may wish to contact Wayne Labenda. Mr. Labenda plans to publish a book about tortoises and can be reached at: 15 North Winifrd Drive, Totowa, New Jersey 07512.

SSAR STUDENT PRIZE COMMITTEE

The SSAR Student Prize Committee for 1977 consists of Robert Bezy, Thomas H. Fritts, Kirkland Jones, Richard Wasserzug and Margaret Stewart (chairperson). The committee awards a cash prize for the best student paper published in the SSAR's Journal of Herpetology.

INFORMATION NEEDED BY FWS ON DRYMARCHON CORAIS COUPERI

The Fish and Wildlife Service now has information on file that the Eastern indigo snake (Drymarchon corais couperi) should be determined to be Threatened. On August 1, 1977, they published in the Federal Register (42 FR 38921-38924) a proposal to make such a determination.

The Office of Endangered Species would appreciate the assistance of you or your colleagues in:
--providing any factual data you may have access to concerning the status of this species;
--advising them of any special considerations that should be taken into account prior to their final determination of the snake's status;
--location of critical habitat;
--providing any other advice or guidance you feel relevant.

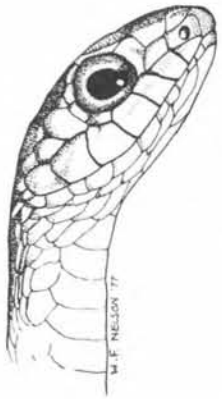
The formal comment period for this proposal expires on October 30, 1977. Direct replies to Jack N. Berryman, Acting Associate Director, Office of Endangered Species, U.S. Fish and Wildlife Service, Washington, D.C. 20240.

DUTCHESS COUNTY NY ZOOLOGICAL SURVEY

Data on reptile and amphibian distributions from Dutchess County, New York are wanted for a study of the vertebrate fauna and habitats of the County. Especially desired is information on uncommon, rare or declining species, or species at geographical range margins. The Survey will generate recommendations for the conservation of rare species and rare habitat types on a county basis. A summary of data is available, and a detailed report is in preparation. Rare species localities information will be used discreetly. Write to: E. Kiviat, Bard College, Annandale, New York 12504.

ABSTRACT OMITTED

The abstract of Dale R. Jackson's paper was inadvertently omitted from HR volume 7 (1976), and is as follows:



Reproductive Strategies of Sympatric Freshwater Turtles in North Florida. Reproductive strategies of four freshwater emydine turtles (Chrysemys nelsoni, C. floridana, C. scripta, and Deirochelys reticularia), which are sympatric in a narrow zone in north peninsular Florida, were determined by ovarian examination and field observation. All are iteroparous, multiple-clutched species which utilize an r-strategem, largely in response to predation losses at early stages. Developmental quiescence (pre-embryonic diapause) at low temperatures enables two species to nest during late fall and winter. Seasonal ovipositional differences may serve as a means of resource partitioning, predator avoidance, or as a response to seasonal resource availability. Dale R. Jackson, Department of Zoology, University of Florida, Gainesville, Florida 32611.

NATURAL HISTORY PRINTS BY DAVID M. DENNIS

FOR THE FIRST TIME wildlife prints by David M. Dennis are being offered for public sale. These portraits are *full-color reproductions* of the original watercolor drawings, each printed on a sturdy paper stock measuring 20 by 24 inches and suitable for framing. Prints are *strictly limited to an edition of 500 copies, each of which the artist has numbered and signed individually.* Because of the relatively small size of the edition and the fact that this is the first offering of Mr. Dennis' work, these prints represent a sound investment as well as a visual delight. They would also be ideal for gifts.

Mr. Dennis is widely known to the scientific community as a wildlife artist specializing in watercolor portraits of lower vertebrates and insects. His self-taught artistry is complemented by his academic training in biology and his personal field experience with each of the animals he paints. Mr. Dennis earned his undergraduate degree in zoology from The Ohio State University in 1966 and since then he has held a succession of positions as biological illustrator at the Columbus Zoological Gardens, the University of Kansas Museum of Natural History and now at Ohio State. He has illustrated numerous biology textbooks including one which he co-authored, but is perhaps best known to vertebrate biologists for the exquisite series of watercolors published in *Hylid Frogs of Middle America* (The University of Kansas Press, 1970). Originals of Mr. Dennis' watercolors have been exhibited in art galleries and museums throughout the United States and also at numerous scientific meetings.

TO ORDER please use the form provided below:

_____
your name (please print)

_____
address *city* *state* *zip*

Please mark the appropriate boxes and fill in the last column.

". . .an essential reference for anyone interested in the amphibians of South America."—from the Introduction.

JIMENEZ DE LA ESPADA

VERTEBRADOS DEL VIAJE AL PACÍFICO: Batracios

with a new introduction by Jay M. Savage, University of Southern California (U.S.A.)

about 250 pages including 7 full-page plates, 7 by 10 inches, originally published in Madrid, 1875

IN 1862 the government of King Carlos III commissioned an expedition of naturalists to study the fauna and flora of South America, a survey which ranks as one of the greatest of the 19th century. The *Comision Cientifica del Pacifico*, with Marcos Jimenez de la Espada as herpetologist, covered 55,000 km during 1862-1865 including the entire Pacific coast as well as Brasil, Argentina and Uruguay, from the Straits of Magellan to the highest Andean peaks in Ecuador. The survey was highly successful in amassing collections, despite the handicaps of disease, inadequate maps and hostile natives.

Espada's monograph contains detailed descriptions of the frogs and toads of South America and a series of excellent illustrations (some shown at left). In addition to the book itself, which has been out-of-print and unobtainable for decades, the reprint includes a new introduction by Professor Savage. This contains a biography of Espada, a table giving the current status of the scientific names of frogs proposed by him, and maps of the *Comision*'s routes in South America.

PRICES & ORDERING

- SSAR members, if ordered before 15 November *$10 clothbound*
- Institutions; non-members; orders after 15 November *$15 clothbound*

Orders may be placed now; book will be published in winter 1977. To take advantage of special prices, SSAR members must place their orders before 15 November. Send orders with payment to Dr. Douglas H. Taylor, Publications Secretary, Society for the Study of Amphibians and Reptiles, Department of Zoology, Miami University, Oxford, Ohio 45056, U.S.A. Please make checks payable to "SSAR"; receipt sent on request only.

CONTRIBUTION TO THE COMPARATIVE CYTOMORPHOLOGY OF HYLID FROGS FROM VENEZUELA. Mercedes L. Acuna. Universidad de Oriente, Cumaa, Venezuela.

The available data from comparative hematology led to the conclusion that there are significant differences among groups of anura from tropical and temperate zones. In order to provide some information about comparative cytomorphology of Hyla from Venezuela, Hyla x-signata, Hyla crepitans, Hyla robertsimoni, Hyla geographica, and Hyla rostrata were selected for the present study.

Blood cell morphology and white cell differential counts were made. On the basis of cytoplasmic staining reactions and corresponding nuclear characteristics as well as size and shape of cells, the morphological features of cell types in smears stained by the Giemsa's method are described. Leucocyte differential counts are also presented by determinations from blood smears. Results and significant differences obtained in this study will be discussed and compared with those from temperate zone frogs.

HEMATOLOGICAL OBSERVATIONS ON SOME ANURANS FROM VENEZUELA. Mercedes L. Acuna and Felicia C. Rodulfo. Universidad de Oriente, Cumana, Venezuela.

The hematology of six species of anurans from the northeastern part of Venezuela (Hyla x-signata, Hyla crepitans, Hyla geographica, Pseudis paradoxa, Bufo granulosus and Leptodactylus fuscus) are compared. Determinations included blood cell counts, hematocrit values, hemoglobin concentrations, and calculations of mean corpuscular volumes, mean corpuscular hemoglobin and mean corpuscular hemoglobin concentrations.

Significant differences among the Hyla were observed in all the hematological indexes. Comparisons of the hematological parameters were made among groups in relation to different habitats. Significant differences were found between arboreal Hyla x-signata and aquatic Pseudis paradoxa. However, no significant differences were observed when the terrestrial Bufo granulosus and Leptodactylus fuscus were compared with the aquatic Pseudis paradoxa. Even though the presently available data are too few to permit more precise statements, the tentative interpretation is that the influence of ecological factors are reflected in the variations of the hematological parameters.

Aldridge, Robert - see Weil

MYOLOGICAL STUDIES ON THE RELATIONSHIP BETWEEN THE ANURAN PREPOLLEX AND PREHALLUX. Marshall L. Andersen. University of Kansas, Lawrence, Kansas.

Hypotheses concerning the relationship between the anuran prepollex and prehallux suggest that the prehallux and prepollex are homologous structures or that the prepollex actually represents the first digit of the anuran manus. Skeletal structure favors the first hypothesis. Recent intensive investigations into the comparative osteology and myology of the manus and pes of 16 families of anurans, however, appears to favor the second hypothesis. The musculature of the prehallux is relatively simple and arises from the plantar aponeurosis. The muscles of the prepollex have a more complex arrangement and arise from the os capitato-hamatum as does similar musculature on the four recognized digits.

REGULATION OF POPULATION SIZE IN A TROPICAL LIZARD, ANOLIS LIMIFRONS. Andrews, Robin M., A. Stanley Rand, and S. Guerrero. Virginia Polytechnic Institute and State University, Blacksburg, VA (senior author) and Smithsonian Tropical Research Institute, Balboa, Canal Zone.

We have been censusing A. limifrons on Barro Colorado Island in Panama since 1971. The population exhibits annual turnover and consistent seasonal changes in age structure primarily as a result of decreased fecundity during the dry season. Population density has fluctuated markedly from year to year. The affect of weather, predation, parasitism, and food availability on survivorship and fecundity has been investigated. Leslie matrix models are used to evaluate the relative importance of the above factors in determination of population density.

INVESTIGATION INTO THE NATURAL HISTORY OF PSEUDACRIS ORNATA IN NORTH CENTRAL FLORIDA-PRELIMINARY REPORT. Ray E. Ashton, Jr., Patricia Ashton, North Carolina State Museum and David Deitz, University of Florida.

Adult Pseudacris ornata were captured in and around cypress head breeding sites at the beginning of the winter breeding season. Frogs were tagged subcutaneously with Cobalt 60 radioactive wire and released. Movements were monitored at 24-48 hour intervals using a Thyac III scintillation probe. Calling sites, microhabitat, movements, burrowing behavior and other activities were noted during and after P. ornata completed breeding activities. This behavioral data is being correlated with weather data, including barometric pressure, using various SAS programming techniques.

During breeding, males utilized grass clumps as major calling sites. During the day and when temperatures and humidity were too low, males burrowed into the grass clump bases, 12-18 cm below the water surface. When water temperatures dropped below 10°C, males left the ponds and burrowed at the base of vegetation clumps. Burrows up to 8 cm in depth were dug by utilizing the hind feet in Scaphiopus fashion.

The only tagged female was originally captured at the edge of the breeding pond. After tagging, this individual moved into an open field 55 m from the site. Eight days later the female returned to the pond and was observed during breeding with a non-tagged male. Immediately following egg deposition the female remained dormant for 5 days just under the leaf litter at the edge of the pond. Temperatures at this site were 6-8°C. At the end of this period the female moved back into the previously used open field where it remained for 2 months. Males remained near the breeding pond edge during this time, never venturing more than 15 m from the pond. Males were subject to high predation during this period. Specific analysis of data is presently being undertaken.

Ashton, Patricia S. - see Ashton, R.

HISTORY OF THE SOUTH AMERICAN HERPETOFAUNA: A PALEONTOLOGICAL APPROACH. Ana M. Baez, Universidad de Buenos Aires, and Zulma B. de Gasparini, Museo de La Plata, Argentina.

The Cenozoic record of amphibians and reptiles in South America is analysed. All the families recorded in the Lower Tertiary are represented in the Recent fauna, except meiolaniids and sebecids, both of which are extinct. It is evident that among them there are elements of different historical backgrounds that could have joined the South American fauna at different times. Some of those groups, such as pipids, iguanids, pelomedusids, meiolaniids, crocodylids, and perhaps leptodactylids and sebecids, also have Mesozoic records in that continent. Unfortunately most of the earliest records come from southern and eastern South America while the knowledge about the groups inhabiting the northern regions is still poor.

Prior to the connection of the Americas in Plio-Pleistocene times other families appear in the fossil

record, e.g. Testudinidae, Trionychidae, Colubridae, Emydidae?, Nettosuchidae. Except the latter, those groups may have reached the continent from the north, possibly by waif transport.

The absence of many families that comprise the Recent herpetofauna in the fossil record could indicate that they are late immigrants. Nevertheless some of them, according to their degree of endemism and phylogenetic relationships, seem to be older members of the South American fauna. Changes in the geographical distribution of the recorded taxa are considered as being related to geological events of different magnitude which provoked physiographic, and conseuently climatic and floristic changes.

LATE CENOZOIC ENVIRONMENTAL CHANGES IN PRESENT TEMPERATE SOUTH AMERICA. Ana M. Baez and Gustavo Scillato. Universidad de Buenos Aires, Argentina.

Present temperate South America extends approximately South of the Tropic of Capricorn. Besides the Andean area, several major physiographic regions can be recognized: Mesopotamia, Chaco-Pampean plains, Pre-Andean area and Patagonian plateau. By Late Tertiary their basic features were attained due to different geological events; nevertheless consideration of the environmental conditions in Pliocene times is relevant as a basis for the discussion of subsequent changes, which in many cases were gradual as the geological and paleontological data suggest.

There is no general agreement concerning the position of the Plio-Pleistocene boundary. The appearance of Nearctic mammals in South America are the paleontological criterion used. During the Pleistocene extensive areas of the Northern Hemisphere were covered with glacial ice; in the region here considered there were no glaciers extending beyond the foot of the Andes. Moreover, only south of 52°S the continental ice cap reached the present Atlantic coast. The glacial cycles of the Andean region should have affected the climatic-ecological conditions, and consequently the distribution of faunas, of the extra-andean regions. Paleozoological data, mainly from the Province of Buenos Aires (a portion of the Chaco-Pampean plains), support fluctuating climatic changes during Pleistocene and Holocene. This is based primarily on the range of variation in taxa whose ecological requirements are known. Other evidences, such as micropaleontological and sedimentological also are considered.

PHOSPHATE COMPOUNDS IN REPTILIAN RED CELLS. Grant R. Bartlett,. Laboratory for Comparative Biochemistry , San Diego, California.

Interest in phosphate compounds of red blood cells has increased greatly since the discovery that 2,3-diphosphoglycerate (DPG), present in high concentration in red cells of most mammals, acts as an important regulator of oxygen transport by its strong influence on the affinity of hemoglobin for oxygen. Bird red cells contain a large amount of DPG for a brief period during embryonic development, but not after hatch, when inositol pentaphosphate (IP5), which markedly reduces the affinity of hemoglobin for oxygen, becomes a major phosphate constituent. The red cells of man, and of other mammals examined, possess no IP5. We have begun a study of the nature and amounts of phosphate compounds in reptilian red cells. The red cells of man, and of other mammals examined, possess no IP5. We have begun a study of the nature and amounts of phosphate compounds in reptilian red cells. The marine turtles, Chelonia mydas and Lepidochelys olivacea, and the land turtles, Chelydra serpentina and Chrysemys scripta, all had, in their red cells, late in embryonic development, rather large amounts of DPG, which disappeared gradually during the first year after hatch. IP5, absent in the embryo, increased slowly during the first year after hatch to substantial adult levels. The iguanas, Iguana iguana and Ctenosaura pectinata, and the snakes, Elaphe obsoleta and Boa constrictor, had no DPG in their red cells, with perhaps traces of IP5, but unusually high concentrations of ATP. Embryonic, juvenile and adult specimens of Alligator mississippiensis had no DPG or IP5 in their red cells and only low concentrations of ATP and other nucleotides. In contrast to the other reptiles, and mammals, the turtle was remarkably similar to the bird.

EVOLUTIONARY RELATIONSHIPS OF FROGS IN THE NEOTROPICAL FAMILY DENDROBATIDAE. James P. Bogart. University of Guelph.

Chromosomal information obtained from several species of dendrobatid frogs may be used to help formulate a phylogeny which is consistant with some current hypotheses based on other criteria. Colostethus and Phyllobates species possess a diploid chromosome complement of 24 which may be related to some species of the elosiine leptodactylid frogs. Dendrobates species possess diploid chromosome numbers of 20 and 18. Intrageneric variations in chromosomal morphology occur and this information may be useful to help distinguish species groupings.

DEFENSIVE BEHAVIOR IN THE PLETHODONTID SALAMANDERS PSEUDOTRITON MONTANUS AND P. RUBER. Ronald A. Brandon, George M. Labanick, Southern Illinois University at Carbondale, and James E. Huheey, University of Maryland.

Both of these brightly colored salamanders have an elaborate defensive behavior, including lateral and vertical tail displays, tail waving and coiling, head tucking and tail slapping, during which a sticky secretion is released onto the skin surface. Larger specimens tend to do more tail slapping and less posturing. Some specimens of both species, upon continuing harassment, became immobile, P. ruber in a nearly straight posture, P. m. diastictus in a tight coil. The tail displays resemble those of red efts, but in other ways defensive behaviors of these Pseudotriton and red efts differ greatly. These differences and the demonstration of skin toxicity in both forms of Pseudotriton argue against the hypothesis that brightly colored Pseudotriton are palatable, Batesian mimics of the highly toxic red efts. They seem to have some protection of their own.

Brandon, Ronald A. - see Huheey

DEVELOPMENT OF THE UROSTYLE DURING METAMORPHOSIS. Arthur E. Branham and James C. List. Ball State University.

The embryological development of the urostyle during metamorphosis (when the union and ossification of urostyle components is taking place is described in five species of frogs and toads: Leopard Frog (Rana pipiens), Chorus Frog (Pseudacris triseriata), American Toad (Bufo americanus), Gray Tree Frog (Hyla versicolor), and African Clawed Frog (Xenopus laevis). These five genera represent five levels of specialization in frogs and toads, from the primitive Xenopus to the advanced Rana. Tadpoles were reared in the laboratory, preserved at various stages of metamorphosis, and the urostyle region of representative specimens serially cross-sectioned and mounted for observation on microscopic slides. Descriptions and

comparisons of the course of development of the urostyle in these five species is presented.

SNAKE COMMUNITIES: A REVIEW WITH SUGGESTIONS FOR RESEARCH. William S. Brown, Skidmore College, New York. William S. Parker, Mississippi University for Women, Columbus, Mississippi.

Field investigations of snakes have generally focused on autecological studies of single species or, less often, on comparative interspecific ecological studies in a given locality. Few workers have been able to undertake the efforts necessary to sample snakes from habitats supporting a diverse snake community over time sufficient to generate significant input into understanding interactions between various snake species as an assemblage. Our studies at dens have afforded opportunity for seasonal captures of large numbers of individuals and have provided detailed demographic data for comparing at least three species. We here synthesize these findings with previous work with relevance to a community approach. Our review focuses on (1) the trophic niche (food overlap, prey preferences, and thermal-habitat interactions in prey selection); (2) the spatial niche (habitat selection, refuging, dispersal, and habitat conditioning; communal oviposition and overwintering); (3) the temporal niche (activity times, seasonal ingress and emergence); (4) energetics and interspecific growth rates; (5) comparative age-specific survival and reproductive rates in a snake community; and (6) species diversity in selected communities of snakes. Difficulties of capturing these cryptic vertebrates, coupled with their seemingly low population densities, have resulted in certain limitations regarding the contribution of studies of this particular group to the advancement of ecological theory. With these constraints in mind, we offer certain guarded suggestions for future studies of snakes at the community level.

SAMPLING HERPETOLOGICAL COMMUNITIES BY A REMOVAL METHOD. R. Bruce Bury. National Fish and Wildlife Laboratory, Fort Collins, Colorado.

Extensive censuses of amphibian and reptile communities are rudimentary. Line transects alone are often poor indicators or inapplicable for measuring herpetofaunas in many habitats.

A removal technique is proposed as a useful tool to determine the species diversity, relative abundance, and estimated biomass of multi-species complexes in varied habitats. This system provides statistically sound comparisons both within and between communities, and serves as a critical indicator of situations altered by man. The removal method is efficient (2-4 days per plot) and inexpensive. It also appears to effectively sample resident populations of amphibians and reptiles.

Representative examples are provided on removal estimates for diurnal desert lizards and for amphibians in a temperate forest.

THE PHYSIOLOGICAL AND BEHAVIORAL MECHANISMS THAT RELATE TO FEEDING STRATEGIES OF REGINA SEPTEMVITTATA DURING ENVIRONMENTAL TEMPERATURE EXTREMES. Joseph A. Butler - Ohio State University. (Presented by title only)

The queen snake, Regina septemvittata, is a semi-aquatic reptile of the mid-eastern United States. It has been stated in several previous studies that this snake feeds almost exclusively on crayfish. If this is the case the snake is exposed to extremely cool water temperatures while feeding during the spring and fall.

The Galapagos marine iguana feeds in water which is below its preferred temperature. This animal meets this stress by physiologically thermoregulating by decreasing conductance below expected levels in the water. My experimentation has shown that the queen snake cannot decrease conductance appreciably while in the water.

Some fish have evolved enzyme systems which allow them to be active over wide thermal ranges. It is generally accepted that at least terrestrial reptiles have not been pressured to evolve such enzymes due to the wide variety of microhabitats available in terrestrial environments and because reptiles may behaviorally thermoregulate. My studies have shown that the enzyme myosin ATPase of R. septemvittata is most active near 28C (i.e. near eccritic and preferred temperatures of this animal). If this enzyme cannot be acclimated to function at lower temperatures (which I have not shown) the animal must be functioning in a different manner.

One possibility is that the snake feeds on more terrestrial prey during these cold periods and switches to crayfish when water temperatures are more favorable. Stomach contents are being collected and classified according to season. Results are scanty at present as more samples are needed but if there is a seasonal difference in prey taken this could explain how this snake copes with temperature extremes. If no difference is found the possibility of low temperature acclimation of the enzyme myosin ATPase must be considered.

NEW RECORDS OF COLUBRID SNAKES FROM PERU, WITH NOTES ON THEIR ECOLOGY AND DISTRIBUTION. Nelly C. de Espinoza, Museo de Historia Natural "Javier Prado", Apartado 1109, Lima, Peru.

The following 18 species of colubrid snakes are reported from Peru: Atractus occipitoalbus, Chironius cinnamomeus, C. flavolineatus, C. monticola, C. laevicolis, Dipsas indica ecuadorensis, Dryadophis danieli, Drymobius chloroticus, Drymarchon corais melanurus, Leimadophis fraseri, L. melanostigma, L. oligolepis, L. typhlus forsteri, L. triscalis, Pseudoeryx plicitalis mimeticus, Sibon nebulata leucomelas, Thamnophis proximus, and Xenodon merremii.

ANALYSIS OF THE HERPETOFAUNA OF FLORIDA LONGLEAF PINE-TURKEY OAK (SANDHILL) HABITAT. Howard W. Campbell. National Fish and Wildlife Laboratory, Gainesville, Fla.

The Sandhill habitat in Florida supports a community of 55 plus species of amphibians and reptiles, with at least 19 species of amphibians and 36 species of reptiles. Of these none are considered to be endemic to the habitat, 11 are restricted to habitats with similar physical characteristics, and the rest range throughout a variety of habitats.

Within-habitat resource partitioning is achieved through a complex of spatial and temporal utilization strategies. The composition of the community is regulated by numerous physical factors including nature of the substrate, fire frequency, ground cover and surface water distribution, as well as geologic history.

TECHNIQUES FOR HERPETOFAUNAL COMMUNITY ANALYSIS. Howard W. Campbell and Steven P. Christman. National Fish and Wildlife Laboratory, Gainesville, Fla.

Herptofaunal community analysis has been hampered by the lack of adequate sampling procedures and techniques. The great diversity of habitus, habitat and habits represented in the various groups studied by herpetologists has raised serious obstacles to the development of standard, cross and even within-group, sampling procedures. We view the development of such procedures as one of, if not the most, imperative needs

in the establishment of any effective approach to the analysis of herp communities.

We have developed a sampling approach that utilizes can traps and funnel traps placed in a "plus" shaped pattern with 18" high fences which has proven effective in a variety of habitats in Florida and could be of use in many other areas and habitats. The design was selected to maximize home range intercepts while minimizing cost of materials. A comparison with data obtained from other sampling programs in the same habitats indicates that the system is capable of providing a broad picture of the reptile and amphibian community in a relatively short period but that specialized sampling techniques are still required for certain species in any habitat.

Campbell, Howard W. - see Scott

TEMPERATE HERPETOFAUNAS: PATAGONIA. Jose M. Cei. Instituto Biologia Animal, Universidad Nacional de Cuyo, Mendoza, Argentina.

A general survey of the evolutionary development of the Tertiary Patagonian Biota is given. Paleontological and paleoclimatic evidence points out the remarkable similarity between preglacial ecological conditions of central and western Patagonian lands and both the xeric Chacoan and the humid Chilean ecosystems. The relationships between the Oligocene batrachofauna of Chubut and the present Antartandic batrachofauna are briefly analyzed. The available information on the Cenozoic reptilian fauna is reviewed, and the present composition and regional trends of the Patagonian herpetofauna are discussed.

Northern or ancient Patagonian and a southern or Deseadan major animal habitats are defined and morphologically and/or phytogeographically characterized. Fundamental herpetofaunal associations of the ancient Patagonian major animal habitat, between 38^{o} and 44^{o} South Latitude, are related to the steppe climax, to the western volcanic highlands of Neuquen, Rio Negro provinces and to the isolated basaltic Somuncura Plateau. Endemism and geographic variation of significant members of these communities are analyzed. Herpetofaunal districts of the southern Patagonian, or Deseadan major animal habitat also are recognized. They are the extensive Central highlands of Santa Cruz, the isolated volcanic Meseta near Buenos Aires Lake, the southernmost or Magellanian region of the continent and the San Jorge Gulf coastal association.

The origin and evolution of the present Patagonian herpetofauna are analyzed, and ecotonal forms and endemic forms are compared. The biogeographical patterns of northern Patagonia are pointed out, and the evolutionary importance of the extra-Andean group of primitive telmatobiine frogs is emphasized. These isolated anurans live in the western basaltic lagoons and on the Somuncura Plateau, where they are sympatric with another endemic, monotypic telmatobiine genus, which inhabits warm spring waters.

Evolutionary trends and speciation of the Patagonian genus Liolaemus are discussed. The saxicolous elongatus-kriegi group and the fossorial, psammophilous fitzingeriboulengeri group, are proposed and discussed. A kingi-archeforus group and a magellanicus group are also recognized on the basis of morphological and physiological characteristics. General conclusions on the post-Pleistocene evolutionary radiation of Patagonian lizards are presented.

ENERGETICS IN DIFFERENT LIFE HISTORIES OF AMBYSTOMA TIGRINUM. R. Christopher Chambers. Texas Tech University.

In West Texas Ambystoma tigrinum exhibits life history strategies ranging from a quickly developing aquatic larval stage culminating in metamorphosis to reproductively mature "larvae" which never metamorphose, or neotenes. Lipid deposition and depletion, reflecting energy allocation, has both an ontogenetic and seasonal component. These were isolated by sampling monthly for one year from a permanent neotenic population and from various temporary ponds which held larvae at different stages of development. Carcass and caudal lipid levels and fat body and gonadal weights were analysed separately by covariance analyses with total lean dry weight as the covariate.

Larvae initially have larger carcass lipid deposits than caudal and fat body lipid reserves. Caudal levels surpass carcass deposits before metamorphosis with fat body weight negatively correlated with ovarian weight. All components show significant positive correlation with body size. Immatures from the neotenic population show a similar ontogentic pattern.

Mature neotenes exhibit greater variation in caudal than carcass deposits with an increased lipid level in April and May. Both lipid compartments show a positive relationship with body size; females possessing more body lipid than males. Ovarian weight, the most labile component, shows negative correlation with fat body weight and positive correlation with body size prior to oviposition in November.

Significantly higher lipid levels in the neotenic population reflect higher prey densities in the permanent pond. In all populations selection favors rapid growth and gonadal development. Egg laying before metamorphosis increases fecundity. High lipid deposition rates and paedogenesis increase fitness by allowing flexibility in life history patterns.

Christman, Stephen P. - see Campbell

THE HERPETOFAUNA OF FLORIDA SAND-PINE SCRUB. Steven P. Christman. National Fish and Wildlife Laboratory, Gainesville.

The unique Sand-pine scrub habitat is endemic to Florida and is rapidly disappearing. Although the habitat includes no permanent fresh water, species diversity of terrestrial reptiles may be higher in scrub than any other habitat in Florida. Over 40 species of amphibians and reptiles have been recorded from scrub and at least two are essentially restricted to it. Species diversity and species assemblages appear to change with scrub maturity. Sand-pine scrub is maintained by periodic fire, without which succession to hammock would occur resulting in extirpation of much of the highly-adapted scrub fauna.

Colbert, Sylvia - see Ralin

CINEMATOGRAPHIC TECHNIQUES IN HERPETOLOGICAL EDUCATION. Alan D. Collier. Miami University, Hamilton, Ohio.

Struck by the lack of good herptile films useful for general zoology classrooms (excluding National Geographic televised specials), an attempt was made to formulate a filmed introduction to herptile behavior suitable for wide-range use.

The feeding behavior of selected reptiles and amphibians was chosen because it is the most active and easily photographed behavior. The herptiles filmed were selected on the basis of availability and subsequent film results, also for their general audience recognition.

Attempts were made to document anecdotal reports and explore heretofore unresearched herptiles. Also, behavior that might have been disturbing to viewers was eliminated as not to detract from its educational value.

The finished product is now being used in zoology classes at Miami University's Hamilton Campus. A

second, more detailed film suitable for more advanced classes is now underway.

VARIATION OF DIEL ACTIVITY OF A CHIHUAHUAN DESERT LIZARD COMMUNITY. F. Michael Creusere and Walter G. Whitford. New Mexico State University, Las Cruces, New Mexico.

The diel activity of the ten species that make up a Chihuahuan Desert lizard community can be divided into four main patterns: (a) unimodal throughout most of the day; (b) unimodal for a brief period only, usually morning; (c) bimodal, but with emphasis on early morning activity and (d) true bimodal activity. Species packing in this community was examined on the basis of temporal patterns of activity and microhabitat use.

Lincoln Index population estimates for Cnemidophorus tigris and Holbrookia (Cophosaurus) texana usually indicated densities 3X to 4X that observed at any point in time. Both species were continuously active throughout the day. However, individuals were not necessarily active throughout the day. Most had well defined activity periods occurring in five patterns: (a) early morning activity only; (b) mid-day activity only; (c) late afternoon activity only; (d) both early morning and late afternoon activity and (e) activity throughout the day. Those individuals active at mid-day were usually large males restricted to narrow, arroyo sub-habitats. Females of both species ceased activity from two to six weeks, moving from the population to lay eggs in other habitats.

Small males and some females of most species had their activity restricted to subhabitats not used by the population as a whole and had more restricted activity periods. In all species variability in activity pattern of both sexes was related to the breadth of activity for the species i.e. in species with restricted activity patterns individual variation was small.

THE SIGNIFICANCE OF REPRODUCTIVE ECOLOGY IN FROGS AND ITS RELEVANCE TO THE STUDY OF ANURAN COMMUNITIES. Martha L. Crump. University of Florida, Gainesville, Florida.

The following aspects are important components of anuran community ecology: (1) species diversity (both richness and equitability components), (2) resource utilization (niche breadth calculations of at least the three basic niche dimensions--food, space, and time), (3) community stability (extent of fluctuation of the component population sizes and an analysis of the factors controlling population levels), and (4) interactions of the members of the community (extent to which species limit each others' activities).

Species that depend upon standing bodies of water for reproduction frequently migrate to breeding sites. This results in mixed-species assemblages different from the communities during the non-reproductive periods. In addition, larval communities are entirely independent of the adult communities. Therefore, it is necessary to analyze the four aspects mentioned above for all three types of communities. This "poly-community" phenomenon has an effect on population fluctuations of frog species and on their resultant intra-community interactions. The other components of the community (prey and predators of frogs) are likewise affected by this extremely dynamic system.

It is during the breeding period when most potential species interactions would be expected to occur and when competition for limited resources would be at a maximum. The obvious question is "How can such a high number of species coexist in a restricted area?" Analysis of behavioral isolating mechanisms and resource utilization provide answers in terms of species-specific requirements.

Reproductive strategies have a profound effect on community stability and species diversity. In aseasonal environments where reproduction is continuous, clutch sizes are smaller, but more clutches are produced per year. The result is a buffering against adult population fluctuations, yielding greater community stability and a potential for increased species diversity. Aquatic larval communities are generally characterized by highly fluctuating population sizes due to catastrophic and unpredictable phenomena (such as the evaporation of the site) and high predation pressures. Age-specific mortality (especially high at gastrulation, hatching, and metamorphosis) has obvious significance to community stability.

Another important aspect of reproductive strategy is mode of reproduction (combination of ovoposition site and type of development). An increase in the diversity of reproductive modes results in greater resource partitioning. A world-wide survey of reproductive modes reveals a greater diversity in aseasonal environments than in seasonal environments. Areas high in species richness exhibit a concomitant high diversity of reproductive modes. Mode of reproduction has obvious implications to genetic variability of a population. The most generalized species (those depositing eggs directly in water) breed in the most unpredictable environment and produce the largest clutch-sizes--and therefore exhibit the greatest potential for high genetic variability.

Crump, Martha L. - see Kaplan

AGGRESSIVE BEHAVIOR IN THE GREEN SALAMANDER, ANEIDES AENEUS. Paul V. Cupp, Jr. Eastern Kentucky University.

During June-July, 1976, aggressive interactions were observed between male green salamanders, Aneides aeneus, when single males were introduced into a test chamber already inhabited by a resident male. Of 49 such introductions, 45 resulted in aggressive encounters after which one of the males would retreat. Resident males were usually the aggressors and were victors in 43 of the 45 aggressive encounters. Introduced males returned the aggression in only 11 instances and were victors in only two of the encounters. An aggressive encounter usually consisted of the aggressor rapidly biting and/or vigorously pressing his snout along the back of the other male. In six encounters, prolonged bite-holds were observed in which the jaws of one male would grip the mid-body region or a limb of the other male. These data indicate that A. aeneus is territorial, which may result from competition for favorable rock crevices. Also, this behavior may enhance the chances of a resident male having a successful reproductive effort.

EFFECT OF TONGUE REMOVAL ON THE FEEDING BEHAVIOR OF AN ADULT GARTER SNAKE THAMNOPHIS SIRTALIS. W. D. Denny, G. M. Burghardt, and R. P. Saunders. University of Tennessee.

In two experiments, we attempted to assess the relative importance of the vomeronasal and olfactory systems in garter snakes. Snakes used were an adult T. sirtalis sirtalis which had its tongue surgically removed as an adult several years previously, and three normal T. sirtalis controls. In Experiment 1, the tongueless animal and a control were placed separately for a number of trials in a chamber in which the odor of the nightcrawler Lumbricus terrestris was then introduced. Snakes were then allowed access to Lumbricus pieces. The unusual feeding behavior of the tongueless snake, which consisted of lunging around the cage with mouth wide open, a pattern not seen in any of the control animals, seemed to disrupt the normal

feeding sequence of stalk and attack. We attributed this animal's bizarre feeding behaviors, which seemed to be triggered by the odor of the prey items, to its tonguelessness. In Experiment 2, the tongueless animal and 3 controls were presented with prey items, first with no extra prey odor present and second with odor introduced. All three controls showed decreased latencies when the prey odor was introduced while the tongueless snake showed an increase in latency. Results suggest that the loss of the tongue decreased the ability of this snake to locate prey in an ambiguous olfactory situation.

REPRODUCTIVE CYCLE AND FEEDING BEHAVIOUR OF CUPRIGUANUS ACHALENSIS (SAURIA IGUANIDAE). di Tada, Ismael; R. Martori; B. Kufner y A. Ocana; Centro de Zoologia Aplicada, Universidad de Cordoba, Argentina. (Presented by title only)

Cupriguanus achalensis is the only lizard that lives in Pampa de Achala (elev. 2,200 mts.), an extra cordilleran relict in Sierras Grandes System, Province of Cordoba, Argentine.

Based on field observation a population of Cupriguanus achalensis was studied during the active period of the specie from September to April.

The reproductive cycle presents the following seasonal variations: espermiogenesis begins in September and spermatozoa are present in October and November, in this period copulation occurs. The size and weight of testes decease in December and January, and increase at the end of the summer or beginning of autumn.

Egg development begins in October and laying occurs in January. Hatchings were found from December to January, a year after deposition.

The daily feeding activity is resumed in a simple model. Cupriguanus achalensis is a generalist and he behaves as predator and a primary consumer. Activity begins when the sustratum temperature reaches 22C.

This specie uses a passive strategy (sit and wait) to capture arthropods and active (search) to eat vegetals. The ingestion sequence of an arthropod and other, and an arthropod and a vegetal indicate a predation preference.

These data are correlated with climatic phenomena and food disponibility.

ORIGIN AND DISTRIBUTION OF REPTILES OF LOWLAND TROPICAL RAINFORESTS OF SOUTH AMERICA. James R. Dixon.

Of the 203 reptile genera occurring in South America, approximately 175 (86%) appear to have their origin on that continent, and of the 175, 72 (41%) appear to have evolved within lowland rainforest situations.

Of approximately 1,100 species of South American reptiles, 550 (50%) occur within the boundaries of lowland (- 1000m) tropical rainforests that comprise about 42% of the standing vegetation of South America. Of the 550 reptile species, about 300 (54%) are endemic to the forests and 74% of all South American reptile genera are involved in the forests to some degree.

The South American rainforests have contracted and expanded through the Pleistocene glacial and interglacial periods, often being connected by a series of rainforest corridors of various dimensions, allowing for repeated dispersal of Amazonian reptiles into the Atlantic and Choco forests. There appears to be little migration from the latter into the Amazon forest. The Atlantic and Amazon forests have been most frequently in contact with each other, while the orogeny of the Andes in the Pliocene effectively restricted movements of Amazonian reptiles into the Choco forest.

Prior to the orogeny of the Andes, there appear to have been widespread tropical conditions that allowed aquatic reptiles (crocodiles, turtles,Dracaena) to become well established over much of the area. However, later climatic and geologic events caused extinction of several aquatic species, as evidenced by fossil lowland rainforest species at relatively high (2000m) elevations.

The life style of the modern reptiles of the lowland tropical rainforests is primarily terrestrial (43%), followed by arboreal (26%) fossorial (21%) and aquatic (10%). Many of the terrestrial forms occupy open, semiopen and/or modified forest zones. Some of the latter are surviving relics from Savannah formations of glacial periods, some are perianthropic and the remainder generalists. Only a few species of Andean genera have successfully invaded the lowland tropical rainforests.

As one would expect, the Choco Forest reptile fauna is closely allied to the fauna of Central America while the Atlantic reptile fauna shows less endemism, fewer species and a close affinity to the Amazon Forest fauna.

Though the theory of lowland tropical rainforest refugia during glacial maxima may explain the occurrence of endemism through isolation, the high number of endemic fossorial forms of reptiles may have evolved through changes in edaphic and climatic factors, independent of forest refugia. This may also explain the low number of endemic aquatic reptiles.

Dole, Jim W.--see Durant.

INTEGUMENTARY STRUCTURES CORRELATED WITH URICOTELY IN AN AFRICAN TREEFROG. Drewes, R. C., (California Academy of Sciences), S. S. Hillman, (University of California, Riverside), R. W. Putnam, (UCLA), and O. M. Sokol, (Stanford University).

Uricotely, low evaporative water loss, and high rates of water uptake through the ventral surface have been demonstrated in Chiromantis petersi Boul., an African rhacophorid treefrog (Drewes, et al., in press), placing the species on a par with its congener, C. xerampelina, and with the South American hylid, Phyllomedusa sauvagei Boul. Detailed examination of the anatomy of the integument of C. petersi and comparison with skin samples taken from some 60 other frog species reveal a unique arrangement of chromatophore units in the dermis which appears to be correlated with low EWL and high rates of water uptake.

THE ACOUSTICAL NICHE: AUDITORY RESOURCE PARTITIONING IN ANURAN COMMUNITIES. William E. Duellman. University of Kansas.

Frogs have a limited vocal repertoire; yet within any given multispecies breeding congregation each species has a distinctive call. Moreover, in different habitats or in geographically distant areas similar kinds of calls are produced by different species of frogs. Calls of 39 species of hylid frogs from three widely separated areas (Puerto Viejo, Costa Rica; Belem, Brasil; and Santa Cecilia, Ecuador) were analyzed for seven parameters: 1) number of notes per call group, 2) note repetition rate, 3) number of secondary notes, 4) duration of note, 5) pulse rate, 6) fundamental frequency, and 7) dominant frequency. Cluster analysis revealed that those species having the most similar calls are members of either widely separated geographic communities or different ecological communities within a given area. Discriminant function analyses of individual breeding congregations revealed that 100 percent discrimination is accomplished by utilizing only two or three parameters of the calls. These results suggest that the acoustical parameters of anuran breeding congregations can be viewed as ecological resources in which there is no overlap in utilization within a breeding congregation. Thus, distinctive acoustical niches are evident within anuran communities, and allopatric species fill equivalent niches in different communities.

ORIGIN, EVOLUTION AND DISPERSAL OF THE ANDEAN HERPETOFAUNA. William E. Duellman. University of Kansas.

The herpetofauna of the high Andes consists of two major assemblages. The southern assemblage occurs principally to the south of the Huancabamba Depression in northern Peru. Within this assemblage two groups can be recognized: 1) A Patagonian element of recent invaders of the Andes (Pleurodema, Bufo, Ctenoblepharis, Liolaemus, Phymaturus, Pristidactylus, and Tachymenis), none of which extends north of the Huancabamba Depression; and 2) A mid-Andean element composed of Telmatobius and Stenocercus (both extending north of the Huancabamba Depression) and Batrachophrynus (central Peru). The northern assemblage is composed of three groups: 1) A major northern Andean element made up of Bolitoglossa, Eleutherodactylus, Atelopus, Osornophryne, Colostethus, Cryptobatrachus, Hyla, Centrolenella, Phenacosaurus, Anadia, and Pholidobolus, none of which occurs to the south of the Huancabamba Depression, plus Phrynopus, Gastrotheca, and Proctoporus, all of which occur to the north and south of the Huancabamba Depression. 2) A derived element in the Merida Andes sharing Bolitoglossa, Eleutherodactylus, Atelopus, Colostethus, Hyla, Centrolenella, and Anadia with the northern Andes in Colombia. 3) A partly shared and partly independently derived fauna in the Sierra Nevada de Santa Marta with the endemic Geobatrachus, species of Eleutherodactylus mostly related to species in the Cordillera de la Costa in Venezuela, and three genera (Bolitoglossa, Atelopus, and Cryptobatrachus) shared with the main northern Andes. The members of the northern assemblage are either congeneric with species in the adjacent humid tropical lowlands or are derived from lowland groups.

The herpetofaunas on the humid slopes of the Andes are composed of many endemic species and some endemic genera (Amblyphrynus, Rhamphophryne, Amphignathodon, Centrolene) that are related to taxa in the humid tropical lowlands and related or not to taxa in the high Andes.

The diversity of the Andean herpetofauna is due to: 1) Independent invasions of the Andes by numerous ancestral stocks, and 2) Geographic isolation through expansion and contraction of habitats correlated with altitudinal climatic shifts during the Quaternary. The major physical barriers to distribution are the low depressions--Huancabamba Depression in northern Peru and the Cucuta Depression at the Colombian-Venezuelan frontier. A second factor contributing to broad distributional patterns is the change from an aseasonal humid climate in the north to a seasonal semi-arid climate in the south.

Duellman, William E.--see Pefaur.

ECOLOGICAL DISTRIBUTION OF THE SALIENTIAN FAUNA OF THE MERIDA ANDES, VENEZUELA. Pedro Durant. Universidad de Los Andes, Venezuela.

From August 1970 to October 1971, the main natural areas of the State of Merida were covered in a collecting program along five transects through the western side of the Andes. The areas were selected according to the life zone systems of Tamayo and Holdridge. Each one of the samples collected was identified to species and most of the morphological analysis was done on living material. The distribution of the representative groups of Salientia from these censuses was related to changes in the biophysical conditions from the Parmo or Sub-Alpine life zone to the Tropical wet forest life zone.

About 50% of the 30 genera, and 28% of the 110 species of Salientia in Venezuela are represented in the Merida Andes. The most representative genera are : Hyla (28.4%), Colostethus (18.0%), and Leptodactylus (14.3%). The tropical wet forest harbored about 39.2% of the species collected, and the Paramo only 10.7%. Some species such as C. meridensis and Eleutherodactylus williamsi, seem to be restricted to very specific habitats (Pre-Montane Pluvial Forest and Low Montane Wet Forest, respectively). Others such as Bufo marinus, H. crepitans, and L. podicipinus have wide distribution in most of the life zones of the State of Merida.

AMPHIBIAN ECOLOGY OF THE VENEZUELAN ANDES. Pedro Durant (Universidad de Los Andes, Merida - Venezuela) and Jim W. Dole. (California State University, Northridge).

Some of the biophysical conditions as they change from the Paramo, or Subalpine life zone (3850 m. high, 3-6C biotemperature and 780 mm. rain fall) to the tropical wet forest life zone (62-150 m. high, 28-30^{o}C biotemperature and 3900 mm. rain fall) are discussed. In these environments 50% of the amphibian genera, and 28% of the frog species of Venezuela belong to the Merida Andes alone. Some species (Colostethus meridensis, Eleutherodactylus williamsi, etc.) seem to be restricted to very specific habitats, while others (Bufo marinus, Hyla crepitans, Leptodactylus podicipinus, etc.) are widespread in most of the Andes life zones.

The reproductive cycles and growth of B. marinus and H. crepitans at the xerophytic life zone of the Merida Andes were studied. The supposed nutritional value of some microorganisms found in the gut, the apparent physiological differences in the intestine regions, and the space that the tadpoles of these species occupy in the same pond, all suggest the development of an ecological mechanism in these frogs which allows them to grow in the same body of water while avoiding inter-specific competition effects.

Growth, home range, movements, reproductive activity, seasonal changes in the population structure, significance of food source and differences in the stomach contents before and during breeding season are discussed for Atelopus oxyrhynchus in a Venezuelan cloud forest.

A COMPARISON OF THERMAL TIME CONSTANT OF AQUATIC AND TERRESTRIAL TURTLES. Vickie Earnhart and E. Norbert Smith. Northeastern Oklahoma State University, Tahlequah, Oklahoma.

This study is a review of the literature dealing with turtle thermoregulation. Published heating and cooling rates were compared using thermal time constants and corrected to zero air speed. Data were collected on 9 species of turtles, 5 aquatic and 4 terrestrial.

Regression formulas were then used to calculate weight specific thermal time constants during heating and cooling in each group. For a theoretical aquatic turtle, in air, the warming time constant ranged from16.9 to 203 min. for 0.1 - 10 kg turtles respectively. The cooling time constant went from 24.31 to 174 min. for 0.1 - 10 kg turtles, respectively. For theoretical aquatic turtles in water the warming constant went from 3.2 to 38.4 min. for 0.1 - 10 kg, respectively.

For theoretical terrestrial turtles, (in air) the warming time constant ranged from 23.0 - 375.9 min. for 0.1 - 10 kg turtle, respectively. The cooling time constant ranged from 20.1 - 373.0 min. for a 0.1 - 10 kg turtle.

The ratio of the warming time constant to the cooling time constant (T_W/T_C) was also calculated for each group. For the aquatic turtles in air the ratio went from 0.70 - 1.17 min. for 0.1 - 10 kg, respectively.

The ratio in the terrestrial turtles in air went from 1.15 - 1.01 min. for 0.1 - 10 kg, respectively.

The above observations indicate a profound difference in the heating and cooling response of aquatic and terrestrial turtles. Larger aquatic animals heat much faster than they cool. Large terrestrial turtles cool faster than they heat.

A ZOOGEOGRAPHIC ANALYSIS OF THE HERPETOFAUNA OF THE WEST INDIES. Arthur C. Echternacht. The University of Tennessee - Knoxville.

A quantitative analysis of the herpetofauna of the West Indies is presented. The emphasis is on the relationship between species diversity and area. Sixty-eight islands and their banks are considered. Banks and islands are analyzed separately, as are amphibians and reptiles, and lizards and snakes. Diversity is, in some cases, more closely correlated with bank area than with island area. Amphibian (anuran) and lizard diversity are related to island (or bank) area, whereas snake diversity is related to both area and to diversity of the other groups. This is not unexpected inasmuch as many West Indian snakes prey primarily on other poikilothermic vertebrates.

TERRESTRIAL LOCOMOTION IN SALAMANDERS: GAIT ANALYSIS. James L. Edwards, Michigan State University.

Single-frame motion picture analysis of representatives of the families Ambystomatidae, Dicamptodontidae, Salamandridae and Plethodontidae revealed that all salamanders progress through a typical sequence of gaits. At the slowest speeds, salamanders use a gait previously unreported in vertebrates, in which each limb is in contact with the ground for at least 90% of the stride duration. At faster speeds, the animals switch to lateral sequence, diagonal couplet walks, and then to trots. At the fastest speeds, salamanders abandon their limbs entirely, and "swim" across the substrate in a type of locomotion I call fast lateral undulation. Although any individual will follow the above sequence of gaits, the exact speed at which an individual will switch from one gait to another varies considerably from one locomotor sequence to the next; however, elongate salamanders usually switch to the next fastest gait at lower speeds than more robust forms. Salamanders use only about one-fourth of all terrestrial gaits found by Hildebrand in other vertebrates.

Use of the "walk pattern analysis" of Dagg and de Vos allowed the clustering of salamander gaits into seven similarity groups, which represent "comfortable" locomotor patterns used by large numbers of salamanders. The groups were linked by means of a Prim network to predict how any individual would move from one similarity group to another.

PARTITIONING OF FOOD RESOURCES IN SNAKES OF THE UNIVERSITY OF KANSAS NATURAL HISTORY RESERVATION. Henry S. Fitch. University of Kansas.

Fifteen species of snakes are present on the 239 ha reservation in population densities ranging from 1800 per ha in Diadophis punctatus to less than one per 100 ha in Elaphe guttata. These species differ greatly in size, seasonal schedule, habitat, and their terrestrial. fossorial, arboreal or aquatic adaptations. More than 2500 separate food items have been recorded from snakes on the area. A wide range of prey species are taken, and each species of snake overlaps others in some degree, but in no two does the diet have exactly the same composition. Major food resources are earthworms (mainly Allolobophora caliginosa), voles (mainly Microtus ochrogaster) and frogs (mainly Rana blairi). In all instances of two snake species preferring the same kind of prey, resource partitioning can be shown in: 1) partial habitat separation, or 2) sizes of individual prey items taken, or both.

STRUCTURE AND FUNCTION OF ANOLE DEWLAPS. Henry S. Fitch and Virginia R. Fitch. University of Kansas, Lawrence.

In male lizards of the genus Anolis the dewlap is a highly developed display organ. The species-specific bobbing displays serve varied functions including species recognition, sex recognition, courtship, and maintenance of territory. Females of most species lack dewlaps although their chins may show traces of dewlap color; some have small dewlaps, and a few have them well developed. In the males, size, shape, color, markings and patterns of allometric growth are distinctive of species; squamation is especially complex and varied. Dewlaps having diverse scale patterns are illustrated. Like the display for which it serves, the dewlap itself provides characters that may be indicative of degree of relationship between species. However, except for general color, dewlap characters have not yet been utilized in classification.

THE HERPETOFAUNA OF THE NOTHOFAGUS FORESTS OF SOUTHERN CHILE. Ramon Formas C., Instituto de Zoologia, Universidad Austral de Chile, Casilla 567, Valdivia, Chile.

The herpetofauna of the austral Nothofagus forests is very poor in species but contains many endemic amphibians (Caudiverbera, Telmatobufo, Hylorina, Batrachyla, Rhinoderma, Eupsophus, Insuetophrynus) There are no endemic genera of reptiles. The fauna is composed of some Tertiary anuran elements and of others that migrated into the region (among them some other amphibians and all of the reptiles). The migrant fauna is Patagonian and Andean in origin. Pleistocene glaciation resulted in modifications of distributions. In post-Pleistocene times the Nothofagus forest and its herpetofauna reached more northerly latitudes than at present. There are still some small relictual patches of forest (Valparaiso) where disjunct populations of southern anurans (Batrachyla, Rhinoderma) dwell. The geographic isolation of the Nothofagus forest possibly has permitted intense speciation, especially among the migrant elements.

COMPOSITION, DISTRIBUTION AND ORIGIN OF THE CHACOAN HERPETOFAUNA. Jose M. Gallardo.

The Chacoan herpetofauna occupies the northern part of the Chaco-Bonariensean Plateau having an elevation of 100-500 m. Below 100 m there is a transition to the Litoral-Mesopotamian fauna; above 500 m there is a transition to the Subandean fauna. In this area there is a rainfall gradient generally coinciding with the topography. The vegetation principally is a Chacoan park type with monte and isolated trees interspersed in grassland; thorn bushes or halophytic vegetation sometimes are present. The existence of rivers influence the faunistic distributions.

The herpetofauna is composed of five families of amphibians, six of lizards, five of snakes, one of turtles, and one of crocodilians. There is a total of 46 genera and 63 species. The amphibians and to a lesser degree the lizards have a parallel origin with the Litoral-Mesopotamian fauna. Both apparently originated from the same Guayana-Brasilian stock, which differentiated later through isolation and reinvasion of some areas. The view fits the refugia theory for survival during unfavorable climatic periods with subsequent reinvasion of areas when favorable climates returned. River systems have been fundamental to the

distribution of amphibians. Snakes have a broader distribution and in general do not follow the patterns of amphibians and lizards. Turtles and crocodilians reach farthest west through the rivers; their distributions tend to coincide with those of the fish fauna. The Chacoan herpetofauna seems to have originated from the Parana River fauna, which in the past extended to the west, where it subsequently adapted to the more rigorous climatic conditions. Among the species of the Chacoan herpetofauna are several that show reproductive, dietary and/or ethological adaptations denoting their adjustment to the conditions present on the Chaco-Bonariensean Plateau.

SAMPLE SIZE IN TAXONOMIC ELECTROPHORETIC STUDIES - AN EMPIRICAL ANALYSIS. George C. Gorman, U.C.L.A.

Electrophoretic studies have been used primarily in the analyses of questions related to population genetics. Large sample sizes for such studies are clearly requisite. A carry-over from this approach is that workers assume that sample sizes of 20-30 or more individuals are desirable if not necessary when one is using electrophoresis primarily for taxonomic analyses. Theory suggests otherwise. Dr. M. Nei and co-workers have pointed out that increasing the number of loci sampled is far more important than increasing the number of individuals sampled for a taxonomic comparison.

Empirical analysis of previous studies on the relationships of insular Anolis lizards supports theory rather convincingly. Genetic distance estimates are remarkably insensitive to sample size for number of individuals. A randomly chosen individual from the population will often be sufficient. The error in genetic distance estimates is far greater by decreasing the number of loci sampled, than by decreasing the number of individuals sampled.

Even heterozygosity estimates are relatively insensitive to sample size. Ten individuals appears to be sufficient for most purposes. Even two individuals ususally gives the correct "ballpark" estimate.

THE ECOLOGY OF THE SPECTACLED CAIMAN IN THE VENEZUELAN GUAYANA. *S. J. Gorzula. I.V.I.C. - Caracas 101, Venezuela.

For three years a population of spectacled caimans, Caimancrocodilus crocodilus, has been studied using mark and recapture techniques. The caimans occur in a savanna lagoon system that consists of 4 permanent and 9 temporary lagoons. During the dry season the lagoons cover 2.28 hectares, and during the rainy season 23.32 hectares.

Migration to temporary lagoons occurs in the rainy season. Such migrations occur on nights when it is raining, and the caimans frequently return to the permanent lagoons on the same night. Caimans, displaced from their lagoons, will home up to 2 km.

A growth curve was made from the data of 36 recaptured caimans. It was estimated that in this area caimans take 6 years to reach a total length of 97 cms. Thereafter the growth rate varies from year to year. During a dry year there may be no growth at all, and during a wet year a large caiman may increase in length by up to 10 cms.

During the first two years of life, the young caimans stay near the site of the nest, and eat terrestrial insects. Older caimans eat insects during the dry season, but during the rainy season migrate to temporary lagoons and eat frogs. Although there are 26 species of frogs that breed in the area, only three species--Bufo granulosus, Elachistocleis ovalis, and Pleuroderma brachyops--were found in the stomach contents of the caimans.

BEHAVIOR, ECOLOGY, AND THE ADAPTIVE ZONE OF AFRICAN MOLE VIPERS (ATRACTASPIS). Harry W. Greene. University of Tennessee, Knoxville.

Morphological and biochemical studies by others suggest that mole vipers are related to aparallactine colubrids and not viperids. I will summarize literature records, stomach analyses, and observations on captive A. bibronii and A. microlepidota. Defensive behavior is similar to that of many other small, secretive snakes and includes head hiding, neck arching, body flattening, tail display, body snapping, cloacal discharge, biting, and immobility. Prey killing behavior is unusual and differs from viperids in at least two respects: (i) one fang is used, and the strike is a posterior and/or lateral head movement (rather than a forward movement with two fangs); (ii) single and multiple rodent prey are struck repeatedly before ingestion of any one item begins (rather than a single strike at one item prior to ingesting it). Data are available on 75 prey items in 45 specimens of four species. One snake had eaten an anuran and one contained 12 reptile eggs. Thirty-one specimens contained 1-2 reptiles per stomach ($\bar{x}$=1.13); 11 specimens contained 1-4 mammals per stomach ($\bar{x}$=2.45) Eighteen of 27 mammals (67%) appeared to be nestlings; 9 of 11 stomachs with mammals (82%) had multiple prey. The peculiar prey killing behavior and unusual cranial modifications of Atractaspis are perhaps adaptations for (i) delivery of a venomous bite to a potentially dangerous prey in a confined space and (ii) rapidly immobilizing several prey items (some of which might otherwise escape) prior to ingesting them. (Supported by the Theodore Roosevelt Memorial Fund, the Karl P. Schmidt Fund, and NSF BNS 76-19903).

QUATERNARY BIOGEOGRAPHY OF TROPICAL LOWLAND SOUTH AMERICA. Jurgen Haffer.

Climatic-vegetational fluctuations in the neotropical lowlands during the Quaternary caused vast changes in the distribution of forest and nonforest biota. Comparatively restricted populations of plants and animals probably were isolated and deviated in remnant habitat areas ('refugia') during adverse climatic periods, often reaching the level of new subspecies or species before they established secondary contact with other refuge populations during expansive phases under a favorable climate. Numerous species probably became extinct during the Pleistocene vegetational fluctuations, probably leading to the elimination of entire evolutionary lines.

Results of recent biogeographical studies on neotropical birds, lizards, butterflies, and plants of forest habitats support the refuge theory. A total of about 40 forest refugia have been proposed in Middle and South America, a larger number for plants and insects than for vertebrates. This difference may reflect different survival ability of these groups of organisms in refugia of varying size. Quaternary vegetational fluctuations probably also determined the evolution of nonforest faunas at the level of subspecies and species. Additional direct evidence for the location of Quaternary forest and nonforest refugia based on eomorphological, pedological, and palynological data is needed to substantiate the above conclusions which are largely derived from biogeographical interpretations.

A REVIEW OF STRUCTURING IN HERPETOLOGICAL COMMUNITIES. Harold Heatwole. University of New England, New South Wales, Australia.

A literature review of the structuring of herpetological communites is presented. Structuring is examined from several viewpoints:

1. Numbers of species and individuals in different communities as related to environmental and vegetational features;
2. biomass;
3. spatial relations - relation to environmental geometry and to habitat selection; and
4. community interactions.

Hillman, S. S. - see Drewes

CALL DIFFERENCES AND CALLING SITE SEGREGATION IN ANURAN SPECIES FROM CENTRAL AMAZONIAN FLOATING MEADOWS. Walter Hodl. Zool. Inst. d. Univ. Wien, Austria.

The acoustic behavior of 15 sympatric and synchronically breeding species of frogs in an area of floating meadows near Manaus, Brazil was studied for a period of 8 months. The calling positions of each species can be identified with certain physiognomic types of vegetation.

Sound analyses were used to compare the mating calls. The main variables are dominant frequency, call duration and pulse repetition rate. Each of the 15 species has a distinct mating call and differs from the acoustic behavior of each other one. Eleven species are separated in their dominant frequency ranges within their specific calling sites. Species sharing emphasized frequency ranges within identical calling sites differ greatly in at least two temporal variables.

The roles of calling position, spectral, and temporal features of mating calls in species recognition and premating reproductive isolation are discussed.

DISTRESS CALLS IN CENTRAL AMAZONIAN FROGS. Walter Hodl. Zool. Inst. d. Univ. Wien, Austria.

Distress calls of Hyla lanciformis and H. Boans (juvenile and adult), Leptodactylus ocellatus, L. pentadactylus and Hydrolaetare sp. (adult) are presented in oscillograms and sonagrams. The calls are species-specific, yet showing striking similarities in spectral patterns. A possible protective and communicative function of this call type is discussed.

THE HERPETOFAUNA OF GUIANA, AN APPRAISAL OF OUR CURRENT KNOWLEDGE. Marinus S. Hoogmoed. Rijksmuseum van Natuurlijke Historie, Leiden, The Netherlands.

The Guiana region (bordered by the Orinoco, Cassiquiare Canal, Rio Negro, Amazon and Atlantic Ocean) geologically is one of the oldest regions of South America. The greater part is formed by the pre-Cambrian Guiana-shield, Roraima sandstone covers parts of southern Venezuela and western Guyana, with isolated remnants in central Guyana and central Surinam. The overall elevation of the area does not exceed 1000 m, but the sandstone remnants may reach heights of about 3000 m. Because of their isolated position and their releatively high elevation, these mountains (tepui's) represent subtropical islands in a tropical lowland sea. The total number of reptiles and amphibians known to occur in Guiana at present is 394, of which 162 are amphibians, 232 reptiles. These numbers comprise five sea turtles, one cosmopolitan gecko and five species imported from the Caribbean. The remainder can be assigned to five major groups: endemics; amazonian; widespread; reaching eastern limit of distribution in this area; species reaching Guiana from S. and C. Brazil. Of amphibians 81, of reptiles 64 species are restricted to the Guiana region, or occur only slightly over the borders of the area delimited. The species in the other groups may form endemic subspecies in the area (34 subspecies belonging to 27 species). Most endemics are concentrated in the western part of Guiana, and can be divided into "lowland" and "altitudinal" endemics, the latter exclusively occurring over 1000 m. About 28% of amphibian and 16% of reptile endemics are altitudinal. Endemic altitudinal genera like Otophryne and Oreophrynella seem to represent relics from the early Tertiary, Stefania seems to represent a recent radiation, the position of Riolama is not very clear. The remaining endemic genera (Allophryne, Rhinatrema, Peltocephalus, Amapasaurus) are lowland endemics and their history is not very clear. Endemic species of Elosia and Euparkerella point to relations with SE Brazilian highlands. Most altitudinal endemic species are subtropical derivatives of lower living relatives. The origin of most of the lowland endemics probably is related to the history of the postulated Guiana forest refuge during Quaternary climatic changes. Major geographic barriers are absent for lowland species and differential distribution in most cases probably is due to ecological competition or special habitat requirements. Altitudinal endemics have restricted distributions on one or a few neighbouring tepui's.

NOVEL TOXINS AND THE QUESTION OF WARNING COLORATION AND MIMICRY IN SALAMANDERS. James E. Huheey, University of Maryland, College Park, MD, and Ronald A. Brandon, Southern Illinois University at Carbondale, Carbondale, IL.

It has long been known tht red efts and other American salamandrids are protected by the potent low-molecular weight neurotoxin, tetrodotoxin (TTX). We here report the presence of a second, high-molecular toxin in the skin of Notopthalmus and Taricha which can be distinguished from TTX by its pharmacological and chemical properties. Furthermore, a high-molecular weight, non-TTX poison has been isolated from the skin of salamanders of the genus Pseudotriton. In LD_{50} mouse bioassays (intraperitoneal injection), pseudotritontoxin has comparable toxicity to TTX on a per salamander basis. The finding of these novel toxins requires that the mimetic relationship of these forms, usually considered to be Batesian, be re-examined.

Huheey, James E. - see Brandon

DIFFERENTIATION IN THE GENERA ENYALIUS AND STROBILURUS (IGUANIDAE): IMPLICATIONS FOR PLEISTOCENE CLIMATIC CHANGES IN EASTERN BRAZIL. James F. Jackson University of Southwestern Louisiana.

Geographic variation in meristic and morphometric characters are examined to delimit the taxa of the forest-restricted genus Enyalius in eastern Brazil. Eight taxa are recognized. Phenetic affinities among these are described by multiple discriminant analysis and Wagner networks based on separate morphological data sets. A phylogeny is proposed, and a sequence of allopatric differentiations is hypothesized. The locations of refugia of the Brazilian Atlantic forest during drier climatic periods are hypothesized from present variation in vegetation and precipitation: Santa Catarina refuge, around Baias de Paranagua and Sao Francisco and adjacent slopes of Serra do Mar; Sao Paulo refuge, Serra do Mar between Paranapiacaba and Sao Sebastiao; Bocaina refuge, around Baia da Ilha Grande; Mantiqueira refuge, on Serra da Mantiqueira; Orgaos refuge, on Serra dos Orgaos; Southern Espirito Santo refuge, in the mountains south of Rio Doce; Northern Espirito Santo refuge, on the Coastal plain north of Rio Doce; Salvador refuge, around Baia de Todos os Santos; Pernambuco refuge, along coast of northern Alagoas and southern Pernambuco; Upper Rio Doce refuge, near the headwaters in Minas Gerais. Locations of the hypothesized refugia are compared with the geographical separations in Enyalius proposed to have preceded

differentiation. Differentiation in Enyalius is most interpretable with reference to past forest refugia separated by corridors of open vegetation. Geographic variation in Strobilurus torquatus in northeastern Brazil requires similar conclusions.

THE TAXONOMIC STATUS OF DESMOGNATHUS WELTERI BARBOUR AND A COMPARISON WITH TWO SYMPATRIC CONGENERS. J. Eric Juterbock. Ohio State University.

Abundant morphological and life history evidence exists that Desmognathus welteri Barbour is a full and distinct species and not a giant subspecies of D. fuscus. D. welteri is sympatric throughout its range with both D. fuscus and D. monticola and is more aquatic than either congener. Larvae of D. welteri are larger at hatching than those of either D. fuscus or D. monitcola and maintain this difference throughout larval life. They transform 21-24 months after hatching unlike those of either congener, both of which have larvae which transform no later than nine months after hatching. Adults of D. fuscus are significantly smaller than those of D. welteri and D. monticola. D. welteri and D. monticola have very different types of jaw teeth and patterns of replacement; D. fuscus resembles D. welteri in both regards. All three species have different tail shapes. Color patterns, though variable, show definite patterns of interspecific variation which are characterized. A brief review is made of interspecific differences reported elsewhere for related characters. The known range of D. welteri is described.

THE NON-COST OF BROODING IN AMBYSTOMA OPACUM. Robert H. Kaplan, Brooklyn College of the City University of New York and Martha L. Crump, University of Florida.

Brooding behavior in salamanders ranges from a weak bond between the parent and offspring (mere presence of parent at the egg deposition site) to active defense of the clutch and transporting of the eggs to a more favorable site. From theoretical literature we reason that brooding behavior would not evolve if the cost to the overall fitness of the parent exceeds the benefit. This cost is measured as a decrease in the future reproductive success of the parent. The cost could be generated by energy drains on the brooding parent due to the physical nature of the behavior itself and/or the relatively lower feeding rate which may be associated with the behavior.

Ambystoma opacum is the only member of a primarily aquatic-breeding genus of salamanders that remains with its eggs after terrestrial deposition. In order to determine the energetic cost of this "parental investment," we compared dry weight, total calories, weight-specific caloric content, and ash content in females that had just begun to brood with those near completion of brooding. Differences in these four variables between the two groups are not significant at $P \leq 0.05$. The argument that brooding females are at an energetic disadvantage because they are unable to forage is discarded because the males collected from the area during the same time period also had empty stomachs and intestines. We therefore suggest that there is no increase in energetic cost due to brooding in A. opacum.

DIFFERENTIATION AND HYBRIDIZATION IN THE NATRIX FASCIATA COMPLEX (REPTILIA: SERPENTES): A NONMORPHOLOGICAL APPROACH. Howard I. Kochman. National Fish and Wildlife Laboratory.

Reproductive interactions among freshwater and coastal populations of Natrix fasciata were evaluated on the basis of osmoregulatory criteria. Putative hybrids between water snakes of the fasciata and clarki groups were collected from a brackish creek along the Atlantic coast of central Florida. Captive-born juveniles, as well as snakes collected wild at this site, were experimentally subjected to full-strength seawater for a maximum duration of 20 days. Variational patterns of survival time and dehydration rate suggest secondary intergradation among highly differentiated, though reproductively compatible taxa.

Within populations, body weight correlates negatively with dehydration rate and positively with salinity tolerance. The fact that neonatal N. f. clarki averaged over 38% heavier than N. f. pictiventris may therefore represent a strategy to reduce the osmotic stress of juveniles in saline habitats. The characteristic salinity tolerance of salt marsh snakes. however, is primarily a function of weight-independent strategies, involving low rates of dehydration and an inherent reluctance to ingest seawater.

HERPETOFAUNAL RELATIONSHIPS OF SOUTH AMERICA WITH AFRICA. Raymond F. Laurent.

At first sight, the contrast between the Neotropical and Ethiopian herpetofaunas is so striking that it seems to fit the Matthewsian or Darlingtonian zoogeographic theories (vicariance of the Ranidae with the Leptodactylidae, Agamidae with the Iguanidae, etc). However, the plate tectonics proved such theories to be incorrect. Some recent paleontological discoveries indeed confirm that Africa and South America were united until almost the end of the Mesozoic. Of those preatlantic groups, only a few are now surviving as such: the Gymnophiona as a whole, the Pipidae, the Pelomedusidae, the Gekkonidae as a whole, the Amphisbaenidae, the Leptotyphlopidae, and probably the Typhlopidae. Many are extinct, for example the Mesosuchians, and many other Mesozoic reptiles. The Leiopelmatidae were present in Jurassic times in South America and presumably in Africa as well. A less old wave probably is represented by the Myobatrachidae which also became extinct there except for Heleophryne in Africa and those that evolved into Leptodactylids and Ranoids. The Geotrypetes - Apodops group survived in Africa while the Ichthyophiidae did so only in the Neotropical Realm. Some groups apparently managed to migrate from one continent to the other before the final split. The Bufonidae and the Iguanidae did it from west to east while the Microhylids travelled in the opposite direction. The Iguanidae reached Madagascar where they survived but they did not in Africa.

Some other groups had a similar opportunity but failed to establish themselves on the other continent probably because they prohibit mutual ecological occurrence. The sister groups leptodactylids and ranids are a typical case.

For many millions of years after its birth the Atlantic Ocean was a narrow sea and therefore not a major barrier against rafting dispersal. Kluge demonstrated such crossings as recent as Pliocene or Pleistocene for the Hemidactylus mabouia brooki complex. Quite reasonably, many groups might have been successful in a similar feat during earlier periods. Especially for the Gekkoninae several waves might be considered. In general, the rafting from South America to Africa seems to be a dubious and unusual event (Typhlopidae, Natricidae), whereas the African invaders of South America seem to have been considerably more frequent--not only the Gekkoninae, but also the skinks (Mabuya) and the Gavialidae which died out there afterwards, perhaps also some amphisbaenians and Typhlopidae, the Lycodontinae and the Colubridae (sensu Underwood).

Some groups apparently came from elsewhere in both continents according a Matthewsian or Darlingtonian scheme; these include the Testudinidae, Crocodylidae, Elapidae, and possibly the Lycodontinae, Boiginae, Natricidae and Colubridae.

A round-about Odyssey through northern continents in fundamented for the Ranidae with Rana palmipes as a rather agressive pioneer. An inverse course is quite unlikely but seems a remote possibility for the Boiginae, which are numerous in South America (Leptodeira, etc.) and so far made a modest inroad in Africa (Telescopus).

However, the most numerous groups evolved on only one side of the Atlantic and failed to colonize the other continent. Examples are the Dermophiinae, Caecilidae (sensu stricto) Typhlonectidae, the already-mentioned Leptodactylidae, the Hylidae, Centrolenidae, Pseudidae, Dendrobatidae, Teiidae, Anguidae, Boini, Dipsadinae, Xenodontinae, Crotalinae for South America; the Scolecomorphidae, Herpelinae, Ranidae (except for Rana palmipes), Hyperoliidae, Agamidae, Chamaeleonidae, Lacertidae, Cordylidae, Varanidae, Pythoninae, Dasypeltinae and Viperinae for Africa. A temporary inroad before the Turonian severance or a short-lived beach head on either side are distinct possibilities which paleontological discoveries in Cretaceous and Paleocene beds on the critical coast zones of both continents might substantiate.

THE HERPETOFAUNA OF THE LLANOS AND ASSOCIATED NON-FOREST REGIONS OF NORTHERN SOUTH AMERICA. Juan R. Leon. Escuela de Ciencias Universidad de Oriente, Cumana, Venezuela, S.A.

Considering the great number of species and diversity of South American neotropical amphibians and reptiles, a discussion restricted to llanos species deals with only a tiny fraction of the entire herpetofauna. Since different authors in this symposium will be dealing with other major areas, a good amount of knowledge on the origin, evolution, dispersal and complexity of the neotropical amphibians and reptiles can be gained.

The northern South American flat lands (llanos) mostly occur in Colombia and Venezuela east of Andes, where they range from 0 to 500 meters above sea level. Geologically, the origin and existence of these llanos can be traced back to Plio-Pleistocene. The actual composition and distribution of the herpetofauna of this area is explained as a function of the recent origin, and the climatic, topographic and ecological changes that have taken place subsequently. These changes are thought to have altered the amount of precipitation inducing a relative aridity to this landscape.

The amphibians and reptiles of the llanos of Colombia and Venezuela are presented together with a brief review of adjacent areas like the Caribbean scrub. In general, the herpetofauna of the South American llanos is impoverished considering its relative land extension. Actually, there is not a typical herpetofauna inhabiting the llanos, probably as a result of recent dispersion of faunal elements into this area coming in from adjacent regions, mostly from Amazonian forests, perhaps as a consequence of a high level of adaptation of animals to the arid climatic conditions. On the basis of these two points of view different aspects of the llanos herpetofauna are discussed.

BIOGEOGRAPHY OF THE AMPHIBIANS IN THE ORIENTAL REGION OF THE GUIANAS. Lescure, Jean. Museum National d'Histoire Naturelle, Paris, France.

NO ABSTRACT RECEIVED.

TRACKING AS AN AID IN THE STUDY OF SNAKE COMMUNITIES. Harvey B. Lillywhite. The University of Kansas, Lawrence, Kansas.

Snakes weighing as little as two grams leave identifiable impressions when crawling over finely textured soil surfaces. Dirt roads, dune habitats, and surfaces prepared by scraping or brushing of topsoil have been used as trackways in ecological studies of snake communities in southern California chaparral and desert. Preliminary data point to the usefulness of snake tracks in determining behavioral density, spatial relationships, social behavior, and species composition within communities. In a montane chaparral community it was possible to discriminate reliably among tracks made by the three common species, Crotalus viridis, Pituophis melanoleucus, and Masticophis lateralis. In desert sand environment, individual sidewinder rattlesnakes, Crotalus cerastes, have been followed for distances exceeding 1.8 Km. Data for snake activity in chaparral point to the difficulties of estimating accurately the absolute densities of snake populations by any presently accepted method.

List, James C. - see Branham

REFUGIA, REFUGES AND MINIMUM CRITICAL SIZE:PROBLEMS IN THE CONSERVATION OF THE NEOTROPICAL HERPETOFAUNA. Thomas E. Lovejoy. World Wildlife Fund-U.S., Washington, D. C.

As the face of South America changes steps must be taken to set aside refuges in which the continent's herpetofauna can survive. Contours of endemism as in Pleistocene refugia constitute one means of identifying areas for conservation priority. Contours of species diversity represent another approach. The merits of the two will be discussed. Also, refuges must be above a minimum critical size to retain species over long periods of time. Aspects of this problem will be discussed, as will emerging results on reptiles as contrasted to data available on birds.

THE AMPHIBIANS OF THE LOWLAND TROPICAL FORESTS OF SOUTH AMERICA. John D. Lynch. The University of Nebraska-Lincoln, Lincoln, Nebraska.

The lowland tropical forests (rainforests Auct., below 1000 m) of South America exist as four units: the Trans-andean forests (Choco, Nechi, and Magdalena), the Northern forests (Santa Marta, Maracaibo Basin, and coastal Venezuela), the Central cis-andean forests (Amazonia or Hylaea Auct.), and the Atlantic forests (eastern and southeastern Brasil). These four forests harbor 530 species of amphibians belonging to 13 families (one salamander, three caecilians, and nine anurans).

Endemicity is pronounced; only 26 species (4.9 %) are shared by two or more forests. The Northern forests are most depauperate (39 species) and least distinct (56 % endemicity). The Atlantic forests harbor 183 species (92 % endemic), the Central forests 225 (90 % endemic) and the Trans-andean forests 126 (88 % endemic).

Hylid frogs are dominant in all four forests (Atlantic 38 %, Central cis-andean 37 %, Northern 28 %, and Trans-andean 22 %) as are leptodactylid frogs (Atlantic 37 %, Central cis-andean 24 %, Northern 26 %, and Trans-andean 25 %). The leptodactylids of the Central, Northern, and Trans-andean forests are essentially eleutherodactylines and leptodactylines whereas those of the Atlantic forests are primarily elosiines, grypiscines, leptodactylines, and odontophrynines. Dendrobatid frogs are prominent components of Central, Northern, and Trans-andean forests but essentially absent in Atlantic forests.

Four areas of marked endemism are apparent:(1)the South American Choco, (2) the upper Amazon Basin (Napo-Ucayali drainages), (3) the Guyanas, and (4) coastal Brazil (Rio de Janeiro - Sao Paulo area). Forty-four per cent (233) of all forest dwelling species of South American Amphibia are restricted to these four forest areas.

Many amphibian groups and genera exhibit distributional patterns congruent with Haffer's forest refugia model. Such a model, consisting of waves of advances and retreats of forests, could be used to account for some of the high species densities observed in some groups.

However, amphibians are poorly represented in some of the proposed refugia or core areas. The poor representation may reflect profound differences between forests mediated by seasonality of rainfall. Unlike amniotes or aquatic vertebrates, most amphibians attempt to be terrestrial without the amniote water-conserving mechanisms. The lack of such mechanisms is most apparent in the reproductive strategies of the amphibians.

The high species densities (and endemicities) of Amphibia correlate well with areas of high aseasonal rainfall. In forested regions, such rainfall provides high humidity microhabitats of long duration necessary for the most fragile reproductive modes employed by amphibians (direct development, terrestrial eggs and larvae). Such environments do not of necessity reduce the success of more pedestrian reproductive modes (eggs and larvae in water).

The importance of reproductive mode in providing constraints to or enhancement of dispersal of forest amphibians is demonstrated by observing that a greater proportion of mode 1 and mode 5 species are non-endemic than might be predicted and that fewer mode 6 and mode 8 species are non-endemic than might be predicted if non-endemicity and reproductive mode are not related. If the sensitivity to seasonality of rainfall is an appropriate index to forest fidelity, then groups exhibiting the more sensitive reproductive modes become of importance in drawing inferences about past climates and biogeographic events. The groups exhibiting sensitive reproductive modes include bolitoglossine salamanders and dendrobatid and eleutherodactyline frogs. The two groups of frogs are autochthonous South American forest elements most dominant in the northern forests of South America. In each case, their ancestry may be traced to the forests of southeastern Brasil. The Brasilian groups are in turn derived from leptodactyloid groups in the Austral forest of Patagonia.

Martori, R. - see DiTada

UTILIZATION OF CAVE RESOURCES BY A LIZARD COMMUNITY. William J. Mautz. Cornell University, Ithaca, New York.

A community of three lizard species exploits the resources of a system of caves at Puerto Marquez, Guerrero, Mexico. The caves provide a stable, low temperature, high humidity environment with variable and sparse food resources. Anolis taylori (Iguanidae), Phyllodactylus lanei (Gekkonidae), and Lepidophyma smithi (Xantusiidae) differ in the degree to which they utilize the cave resources. These differences are apparent in activity pattern, body temperature, evaporative water loss, and diet. Specializations for cavernicolous life involve absence of a diel activity cycle, absence of thermo-regulatory activity, low resistence to water loss, and a generalized diet that includes decaying fruit and probably carrion.

Mecham, John S. - see Sattler

THE ENERGETIC BASIS OF SOCIAL BEHAVIOR: LIZARD SOCIAL STRUCTURES. George Middendorf III and Wilfred M. Post III. Graduate Program in Ecology, University of Tennessee.

The mechanisms controlling the specific social structures exhibited by various vertebrate populations are as yet unknown. Although some suggestions have been made of environmental or genetic causality, most investigators have been content to label the social structure as to general type. Investigations of lizards have often contained reports of their social structure; several different types have been reported. These reports are examined for iguanid lizards and other vertebrates where appropriate. Specific attention is paid to environmental conditions of the population under study. From this examination an energetic-based model is proposed in which both population density and resource abundance are seen as crucial factors. Social structures, particularly territoriality and social hierarchy, once thought dichotomous, are seen as points on a spectrum of social hierarchy to social aggregation. These structures replace one another depending upon the environmental conditions. While the concept of a social structure reflecting the environmental conditions is not new, the concept of an energetic-based spectrum of structures reflecting these conditions is. Such a formulation suggests that studies of social behavior should, in addition to examining type and variation of structure, consider the energetic cost to the animals, the associated gain, and, most importantly, consider the structure in relation to the ecological conditions. Until an approach of this sort is used, studies of social structure will remain only descriptive. The social behavior of the iguanid lizard Sceloporus jarrovi is currently being examined utilizing this approach. (Funded by NSF-DEB 76-16841).

ACTIVITY METABOLISM IN THE MUDPUPPY, NECTURUS MACULOSUS. Kirk Miller. Department of Zoology, University of Oklahoma.

Routine and sustained activity metabolism were investigated in Necturus maculosus acclimated at 5°C or 15°C and an LD 12:12 photoperiod. Mudpuppies exhibited significant daily cycles in oxygen consumption and spontaneous locomotor activity at both acclimation temperatures. The majority of the increment of oxygen consumption during periods of high spontaneous activity was due to air breathing. Routine whole body lactate levels did not vary with acclimation temperature or time of day.

Animals from both acclimation temperatures were electrically stimulated to maximum activity for 30 min (complete exhaustion) at two times of day. Animals stimulated to maximum activity during periods of high spontaneous levels and depended entirely on anaerobiosis for extra energy production. Animals stimulated to maximum activity during periods of low spontaneous activity increased oxygen consumption by air breathing but derived the majority of the increase in energy production anaerobically.

Whole body lactate production during maximum activity was independent of acclimation temperature and independent of the level of spontaneous activity at the time of stimulation. Whole body lactate levels remained high for more than 10 h following stimulation but returned to resting levels within 24 h. Salamanders may excrete lactate into the medium but no lactate was found in bladder urine.

Mudpuppies routinely produce 50 - 75% of their energy aerobically, during stimulated maximum activity, however, 67 - 75% of total energy produced is derived anaerobically.

McNulty, John A. - see Schwalm

COMPARISON OF "NATURALISTIC" AND QUADRAT APPROACHES IN THE ANALYSIS OF A BRAZILIAN FROG COMMUNITY. Craig Nelson. Indiana University, Bloomington, Indiana.

Approximately 60 species of anurans occur at the Boraceia Biological Station of the Sao Paulo Museum of Zoology in southeastern Brazil. Three techniques were used for analyzing the habitat differences among the more ubiquitous members of this community. In the first, or "naturalistic", numerous records of site of capture of each species are compared with gross habitat divisions of the station (forest, scrub, meadow, pondside, streamside, etc.). In the second random quadrats were searched. In the third, quadrats were non-randomly placed. In the latter two cases a number of physical and biotic parameters were measured, and weighted and unweighted "niche" breadth and overlap were calculated.

AMPHIBIAN COMMUNITIES IN SOUTHERN INDIANA: FACTORS INFLUENCING SPECIES COMPOSITION IN PONDS. Craig Nelson. Indiana University, Bloomington, Indiana.

Laboratory and field data combined with speculation suggest that three major processes are important in determining the species composition of amphibian communites at individual ponds in southern Indiana. A primary factor is the relative permanence of the pond which largely determines the types, if any, of aquatic vertebrate predators which overwinter in the pond. The nature of the predators in turn is a strong influence on egg and larval survival of spring breeding forms. In several cases it appears that some species are maintained by a stochastic process including escape from predators in good years and nearly complete mortality in other years. Finally, habitat selection and competition among cogeners influence the pool of species available in particular habitats.

TEMPERATURE INDUCED ANOMALIES IN NATRIX FASCIATA. David Wm. Osgood. Butler University. (Presented by title only)

Thirty-four litters of the banded water snake, Natrix fasciata, were incubated under controlled, constant-temperature conditions. The 754 young snakes from these litters were compared with a control group of 20 broods (384 snakes) taken from females caught shortly prior to littering. Of 1,138 young snakes examined, 33 were grossly abnormal in external morphology. The various anomalies can be classified into general groups (shortening of the axial skeleton, bending of the vertebral column, cleft palate, microphthalmia, and reversal of subcaudal scales). Some types of abnormalities were positively correlated with high (30C) and others with low (21C) developmental temperature. The frequency of anomalies was lowest in the 26C treatment group. The incidence of abnormalities in both the 21C and 30C treatment groups was more than twice that of the controls or 26C sample.

SCANNING ELECTRON MICROSCOPY OF EGGS OF SQUAMATA. Mary J. Packard, C. Richard Tracy, and Gary C. Packard. Colorado State University, Fort Collins.

Light microscopy in conjunction with scanning electron microscopy has been used to study the morphology and ultrastructure of "parchment-shelled" eggs from a number of species of Squamata. Shells from eggs fixed in formalin at the time of oviposition and shells from eggs incubated to hatching were examined. In general, "parchment-shelled" eggs are composed of several layers of fibers with a calcareous (=crystalline) layer forming the outermost surface. Both the fibrous layers and the calcareous layer vary in structure and thickness from species to species. The continuity of the crystalline layer is often broken by cracks or fissures which presumably provide for the exchange of respiratory gases with the environment, as well as for the uptake of liquid water from the substate.

COMMUNITY STRUCTURE IN HIGH ANDEAN HERPETOFAUNAS. Jaime E. Pefaur and William E. Duellman. University of Kansas.

Density, diversity, niche breadth and niche overlap were analyzed for amphibians and reptiles in 10 study sites above tree line in the Andes. Two to eight species were found at each site; a total of 1373 specimens of 33 specimens was studied.

Values for speices diverity of the entire herpetofauna show no clear latitudinal trends; there is a significant trend for increasing species diversity in reptiles from equatorial to temperate sites, but there is a comparatively higher diversity in amphibians in the equatorial sites. Two niche dimensions were analyzed fully -- structural habitat and food. Niche breadth values for structural habitat are slightly higher in reptiles than in amphibians. Niche breadth values for food are inverse. Overall niche breadth is higher in amphibians than in reptiles, the former being more generalists than the latter. Niche overlap for structural habitat is higher than for food. Overlap values between any species of pairs in the same community are generally low, with the exception of some pairs of amphibians in which values are relatively high. However, there is no consistent difference in values within and between communities. Unexpectably, niche overlap increases with decreasing species richness and species diversity.

A PRELIMINARY STUDY OF SKIN SURFACE SCULPTURING IN TOADS. David Pettus and Tyler A. Woolley. Colorado State University, Ft. Collins, Colorado.

Specimens from three species of toads (Bufo boreas, B. terrestris and B. woodhousei) were studied by scanning electron microscopy. Skins from four regions of the body were examined at relatively low magnifications (65X and 300X). Surface sculpturing showed considerable variation between regions as well as between species. Well developed channels were present on all species and most regions. The pattern of channels is more reticulate on the ventral and lateral surfaces and more parallel on the dorsum. The skin of B. terrestris is more rugose and spinose than that of the other two species. Too few specimens were used to permit definitive conclusions, but the technique appears promising in working out the adaptive significance of the differences between species.

EFFECTS OF DNA BIOSYNTHETIC INHIBITORS ON BULLFROG TADPOLES DURING THYROID HORMONE INDUCED METAMORPHOSIS. Robert Phillips, James Williams, Wahleah Baker, and Gary VanDenbos. Northeastern Oklahoma State University, Tahlequah, Oklahoma.

The nature of the control mechanisms regulating cell growth and replication in eukaryotic organisms is an active area of research. The anuran system, Rana catesbeiana, provides an interesting animal model for a

number of reasons, especially: a). their existence for extended periods of time in the larval (tadpole) state, and b). the ability to induce metamorphosis precociously with thyroid hormone (TH).

The morphological and biochemical transition which takes place during the metamorphosis climax are interesting from the standpoint of their rapidity and efficiency, and pose the question: to what extent are the developing tissues (ie. limbs, lungs) dependent on pre-formed moelcular components from regressing tissue (ie. tail, gills)?

We are investigating this question by comparing the morphological and biochemical effects of drugs, which inhibit DNA synthesis by blocking specific metabolic steps in the precursor-to-DNA pathway, on TH treated and control tadpoles. One of these drugs, 5-fluorodeoxyuridine is used as a human chemotheraputic agent. The extent to which the dose sensitivity of tadpoles reflects that used to regulate cell proliferation will also be discussed.

This study was supported by NIH grant 1-SO6-RR-08123.

Phillips, Robert - see Williams

ACTIVITY, HABITAT, AND POPULATION STRUCTURE IN THE TURTLE, TRIONYX MUTICUS. Michael V. Plummer. Harding College.

A riverine population of Trionyx muticus was studied for 3 years by capture-mark-recapture. These turtles were most active from May through September. Trapping success was affected by changes in water level, and a midsummer period of inactivity was associated with low, stable water levels and high water temperatures. Males preferred areas with emergent sandbars but females preferred deeper, more open water except during the nesting season when they moved into shallow water adjacent to sandbars. Deviations from parity in sex ratios were attributed to biases in sampling. About 82% of the male population and 25% of the female population was mature. There was a high degree of mobility within and between local subsets of the population; discrete populational boundaries were not observed. Approximately 1900 turtles were estimated to be within a 1.5 km section of river. However, direct counts of all individuals present were not feasible even for small areas, and indices based on capture-mark-recapture were biased by temporary emigration and immigration.

MORPHOLOGICAL VARIATION IN A DIPLOID-TETRAPLOID SPECIES COMPLEX OF TREEFROGS. Ralin, Dennis B., James S. Rogers, and Sylvia Colbert. Kentucky State University, University of New Orleans, Kentucky State University.

A multiple discriminant analysis of 13 external morphological measurements was made on diploid (Hyla chrysoscelis) and tetraploid (H. versicolor) populations. Eastern populations of H. chrysoscelis (South Carolina, Georgia, Ohio, Mississippi) clearly separate from western (south-central Texas) populations when plotted on the first two DF axes. Populations of H. vericolor occupy intermediate positions, but are not very distinct from the eastern diploid populations.

A bivariate plot of the same populations, utilizing indices based on two qualitative characteristics used to define the three formerly described subspecies, shows a similar pattern. Eastern diploid populations plot in the upper right-hand portion of the graph, because most or all individuals have a reticulate pattern on the posterior border of the thighs (1.0) and noticeable webbing between the fingers (1.0). Western diploid populations plot in the lower left-hand portion of the graph, because most or all individuals lack the above characters (0.0, 0.0).

The morphological analyses are consistent with non-morphological data indicating an intermediate origin of H. versicolor, involving two groups of diploid populations. The range of the former subspecies H. v. sandersi corresponds well with that of the western diploid populations. The range of H. v. chrysoscelis (type locality Dallas, Texas) probably included diploid intergrades in north-central Texas and extreme eastern Texas-Louisiana, as well as southern tetraploid populations. The former subspecies H. v. versicolor probably included most eastern diploid populations and northeastern tetraploid populations.

Rand, A. Stanley - see Andrews

USE OF A MAMMALIAN RESOURCE BY A CHIHUAHUAN SNAKE COMMUNITY. Robert Reynolds. University of New Mexico, Albuquerque, New Mexico.

During the summers of 1975-1976 I studied the snake and rodent communities northeast of Chihuahua city. This region is desert scrub with Larrea, Flourensia, Parthenium and Prosopis the characteristic genera.

Snakes were collected along an 80.5 km stretch of route 16. Examination of capture sites for the plant species present, structural characteristics of the vegetation and topographic features showed that snake species exhibited distinct habitat preferences. Rodent species present and their relative densities were assessed by 4500 trap nights at 15 trap stations. Twelve species of rodents were recorded.

Digestive tracts of 274 snakes of 16 species were examined and yielded 121 food items. Rodents comprised 60.68% of the diet by frequency of occurrence, with birds, reptiles, amphibians and arthropods accounting for the remainder. The frequency of occurrence of the rodent species in the snake diets is closely related to their relative densities found by trapping.

The size of the prey was roughly proportional to the size of the predator. Arena experiments in which prey were introduced to a predator show that snakes are selecting prey items on the basis of size and probably not on species. Small snakes selected smaller rodents, whereas large snakes took larger rodents and ignored the smallest species.

The coexistence of the snakes is probably due to differences in the habitat preferences of the snakes and rodents, and is also the result of size differences within and between predator species. Each predator species of a given size class takes a different size class of prey.

COMPARATIVE CRANIAL OSTEOLOGY OF FARANCIA AND PSEUDOERYX: SYSTEMATIC IMPLICATIONS. Douglas A. Rossman, Louisiana State Univ., and David L. Cundall, Lehigh Univ.

Neill (1964) united the montypic North American xenodontine snake genera Abastor and Farancia, and he postulated that Farancia erytrogramma and F. abacura shared a common ancestor with Pseudoeryx plicatilis of

South America. Our examination of approximately 90 skull characters supports the congeneric relationship between the rainbow snake (F. erytrogramma) and the mud snake (F. abacura), but it fails to confirm a close affinity between Farancia and Pseudoeryx. The two genera exhibit their greatest differences in the nasal and orbital regions of the skull. The similarities between Farancia and Pseudoeryx in external features probably can be attributed to convergence. Many skull characters exhibit considerable intraspecific variation, which underscores the need to examine series when conducting osteological studies.

HYBRIDIZATION IN SPADEFOOT TOADS. Paul W. Sattler and John S. Mecham. Texas Tech University.

Hybridization and introgression between Scaphiopus bombifrons and S. hammondi are being investigated with the use of seven electrophoretic species-specific markers. Field studies have demonstrated that significant numbers of hybrids and backcross progeny occur throughout the wide area of sympatry. Experimental laboratory crosses have been made in order to more precisely measure levels of fertility of various hybrid products. Analysis of laboratory hybrids has shown that all but one of the protein markers are inherited codomonately, and so may be used to differentiate between hybrids and offspring from backcrosses. Further, the large number of markers permits identification of the parental species involved in the backcross. Preliminary data does not suggest the occurrence of differential introgression between the two species.

THE ELABORATION OF VENOM DELIVERY SYSTEMS IN SNAKES. Alan H. Savitzky. National Museum of Natural History.

Systems for the injection of venom under pressure through tubular fangs have been developed in at least five lineages of colubroid snakes. Three of these culminated in proteroglyphous taxa, two in solenoglyphous ones. Despite numerous differences between these groups, sufficient similarities exist to recognize common responses to adaptive and mechanical problems. Four components of the venom delivery system may be recognized: venom, fangs, storage lumina, and gland-deforming muscles. Although each of the five proteroglyphous and solenoglyphous groups has developed all four components, other taxa exhibit different combinations of them. Examination of these forms suggests the sequence of modifications leading to fully elaborated systems. Functional coordination among the components of well-developed venom delivery systems enhances the likelihood of convergence in independent lineages of many structural details, including features not immediately related to feeding activities. Although selection favors gradual improvement in the venom delivery apparatus, full attainment of the front-fanged condition consititutes a major adaptive step.

COMPARISON OF CHROMATOPHORE ULTRASTRUCTURE IN NEOTROPICAL HYLID AND CENTROLENID FROGS. Patricia A. Schwalm (University of Chicago) and John A. McNulty (Stritch School of Medicine, Loyola University).

Chromatophore ultrastructure in the infrared-reflecting glass-frog Centrolenella fleischmanni (family Centrolenidae) was found to differ markedly from that of other arboreal green frogs (family Hylidae). Four types of pigment cells are found in the dermis of C. fleischmanni: two correspond in structure to typical hylid xanthophores and iridiophores, one is similar to the unusual melanophores of phyllomedusine hylids (which also reflect infrared light) and one chromatophore type is unlike any cell previously described. A major difference in organization of pigment cells is apparent. The dermis is not primarily composed of discrete groups of chromatophores in associations resembling the hylid dermal chromatophore unit. Instead, flat xanthophores form a continuous sheet just under the basement lamina. This layer is occasionally interrupted by groups of iridiophores that break up the green ground color as a series of light spots. The stellate processes of the new pigment cell also form a continous layer, generally subjacent to other chromatophore types. Pigment granules in the new cell are moderately electron-dense and have an irregular shape that suggests a fluid composition. Melanophores are too few and widely spaced to contribute significantly to the overall appearance of C. fleischmanni. Melanosomes have a fibrous appearance but are smaller and lack the electron-dense inner core of the phyllomedusine melanosomes they resemble.

Implications of chromatophore ultrastructure are discussed in terms of systematics and development.

Scitallo Y., Gustavo - see Baez

SEASONAL SHIFT IN THE TEMPERATURE PREFERENDUM OF THE WANDERING GARTER SNAKE. John R. Scott. Colorado State University, Fort Collins, Colorado.

A constant temperature thermal gradient was used to evaluate preferred body temperatures of spring and fall specimens of Thamnophis elegans vagrans (Baird and Girard) from a montane habitat. Spring animals, which were overwintered at 4°C in the laboratory, maintained significantly higher cloacal temperatures over a 2 day period than animals collected and tested in the fall. Voluntary hypothermia in the fall should be adaptive in that cool retreats (hibernacula) are sought which protect against early winter storms. Hyperthermia in the spring may enhance reproduction and digestion.

THE HERPETOFAUNA OF FOREST LITTER PLOTS FROM CAMEROON. Norman J. Scott, Jr. National Fish and Wildlife Laboratory, Albuquerque, New Mexico.

Systematic samples of African forest litter herpetofaunas were made in Cameroon, Africa. The African faunas are compared with faunas from similar tropical forests of Asia and Central America. Data compared include total species, distribution of individuals among species, and the taxonomic make-up of the samples.

Of special interest are the African samples that were taken from a forest established on a white sand soil. This type of system is generally supposed to be much less productive than tropical forests growing on other types of soils.

THE STATUS OF STUDIES OF HERPETOLOGICAL COMMUNITIES AND SUGGESTIONS FOR FUTURE RESEARCH. Norman J. Scott, Jr., (address above) and Howard W. Campbell, National Fish and Wildlife Laboratory, Gainesville, Fla.

Historical trends in the study of herpetological communities are summarized. Contributions from this session are considered to represent the present "state of the art."

General goals are defined as perceived in these studies and recommendations are made for ways in which these goals can be furthered. Additional ways of looking at herpetological communities are suggested.

LOW FREQUENCIES OF REPRODUCTION IN ITEROPAROUS ORGANISMS. Richard Shine and James J. Bull. University of Utah.

Most vertebrates reproduce every year after maturing, but some, mainly poikilotherms, reproduce at

lower frequencies. Reproducing every second year, or less often, is known in a variety of salamanders, frogs, snakes, lizards, turtles and fish. A simple mathematical model suggests that low reproductive frequencies are at a selective advantage over high frequencies if reproducing entails a large fecundity-independent cost. A large fecundity-independent cost means that even a small clutch entails a high cost (in energy and survivorship) to the reproducing animal. Breeding migrations, territory defense, nest-building and brooding are examples of activities where the costs are largely independent of the number of offspring produced. We make three predictions from this model: (1) species with low reproductive frequencies should show obvious high fecundity-independent costs; (2) within a species, the sex with the highest fecundity-independent cost should show the lowest reproductive frequency; and (3) within a species, the lowest reproductive frequency should be found in the poorest-quality habitat. The data support these predictions.

QUATERNARY BIOGEOGRAPHY OF THE SOUTH AMERICAN HIGHLANDS. Beryl B. Simpson. Smithsonian Institution, Washington, D. C.

The major highland areas of South America include the complex Andean Cordillera, the Pantepui Highlands and the mountains of southeastern Brazil. Quaternary climatic events affected these highlands differently because of their varying ages, elevations and latitudinal positions. The Andean Cordillera which spans about 66 degrees of latitude and reaches elevations over 6000 m, is Cenozoic in age with the highest elevations uplifted only at the end of the Pliocene. The biota of the high Andes thus developed primarily during the Quaternary via immigration from Central America and radiations within the high elevation zones fostered by cyclical climatic changes. Glacial periods, correlated with those elsewhere, were times of ice expansion throughout the length of the Cordillera. In the most northern and southern parts of the Andes, glacial periods were times of range expansion and increased dispersal for supraforest elements: interglacials were periods of population restrictions. Across the Altiplano, the reverse situation applied. In addition to cold/warm cycles, arid/humid cycles variously affected the Andean biota. In contrast to the Andes, the Venezuelan and Brazilian highlands are ancient, in some cases over 1700 million years old. As a consequence of long term erosion, these highlands are lower than those in the western part of the continent and were less drastically affected by Quaternary climatic changes. Biogeographical evidence indicates that the primary Quaternary changes were lowered vegetation zones that allowed increased immigration from other montane regions. The floras and faunas of these highlands are consequently now composed of ancient elements mixed with Pleistocene immigrants.

FOOD RESOURCE PARTITIONING OF BURROWING SAND-PINE SCRUB REPTILES. Charles R. Smith. National Fish and Wildlife Laboratory, Gainesville, Florida.

Tantilla relicta, Eumeces egregius and Neoseps reynoldsi share essentially the same fossorial microhabitat within the sand-pine scrub of Florida. Except for Eumeces egregius (Mount, 1963), little has been reported in the literature on their food habits. Stomach analysis of specimens from several localities in Florida shows considerable differences in their preferred prey. Tantilla relicta is a completely fossorial snake which specializes on tenebrionid larvae. Neoseps reynoldsi also burrows exclusively and feeds on a variety of prey, including termites, lycosids, tenebrionid larvae and ant lions (Neurtoptera). Eumeces egregius, the most surficial of the three species, generalizes on blattids, lycosids and gryllids.

GROWTH AND MOVEMENT OF ALLIGATORS IN SOUTH TEXAS. E. Norbert Smith. Northeastern Oklahoma State University. Tahlequah, Oklahoma.

The growth and movement of the American alligator, Alligator mississippiensis, has been studied at the Welder Wildlife Refuge, Sinton, Texas for six years. Nearly 150 animals have been measured, weighed, sexed, marked and released. Eleven alligators have been recaptured and showed a mean annual weight gain of 8.9 ± 1.7 pounds (4.0 ± 0.8 kg) and 9.4 ± 0.8 inches (23.9 ± 2.0 cm). Rate of weight gain was positively correlated with initial body weight. Rate of length gain was not correlated with initial body length.

Alligators of all sizes were found to move freely between the Aransas River and impoundments on the refuge. Intense collecting activity on the lakes resulted in movement to the river.

Night counts and nest counts were found to be the most reliable method for estimating the population. Mark-recapture estimates are grossly inflated because alligators once caught become wary and are seldom recaptured. The population of alligators at the Welder Refuge appears to have doubled the past 5 years. This is probably the result of federal and state protection for the reptile.

This research was supported by generous grants from: The National Geographic Society, Welder Wildlife Foundation, and the Caesar Kleiberg Foundation.

THE ALBANY PINE BUSH - A NORTHERN HERPETOLOGICAL OUTPOST FOR SOUTHERN SPECIES IN NEW YORK. Margaret M. Stewart and John Rossi. State University of New York at Albany.

The Albany Pine Bush, a pitch pine - scrub oak fire subclimax, has developed on sand dunes deposited as post-glacial Lake Albany drained out the Hudson River Valley. Several species of amphibians and reptiles, absent or rare from surrounding areas, live in the Pine Bush and comprise a community far more like that of Long Island than mid-state New York. Since the fire-controlled dune area is inhospitable to most species, about half as many species live there compared to surrounding areas. At present the Pine Bush supports 26 species while 43 are present in surrounding Albany County.

The "greater" sand plains area of Albany, Schenectady, Saratoga and Warren counties contain the northern-most populations in New York for 9 of the 26 species known from the sand plains. This pattern probably results from migrations of southern species up the Hudson Valley corridor, warmer than surrounding highlands. Distributional patterns of these amphibians and reptiles correspond to those of several plant species and appear to follow patterns of underlying bedrock.

As development encroaches on the Pine Bush, one of the few remaining open areas of the Capital District, populations of several species are being greatly reduced and may be entirely cut off from the main range of the species if not lost. One or more species have disappeared during the last century. Only rigid protection of the area can save these peripheral populations.

THE EFFECT OF CHLORINE ON THE DEVELOPMENT OF RANA PIPIENS EGGS. Betty I. Tarnowski. Butler University. (Presented by title only)

Developing eggs of Rana pipiens were exposed to various chlorine concentrations in a flow through system. A high mortality to developing embryos occurred after departure from the egg jelly at chlorine concentrations of 0.6 ppm and 0.9 ppm. Exposure of embryos to chlorine concentrations of 0.3 ppm and 0.04 ppm did not result in high mortalities following hatching, but increased the time necessary for completion of development. It is suggested that the egg jelly provided protection to the developing embryos since eggs exposed to chlorine concentratons of 0.6 ppm, only while in the egg jelly, showed no high mortality upon hatching or subsequent abnormal development. Survivors of the 0.6 ppm exposure through test duration resulted in chlorine-related abnormalities seen as a reduced body length and twisted tail. An analysis of chlorine-exposed egg jelly is in progress to determine if the egg jelly prevents contact of chlorine with the egg by chemically reacting with the chlorine.

GENUS, OR SUBGENUS: THAT IS THE QUESTION. Robert A. Thomas. Texas A&M University.

Current studies of certain Neotropical xenodontine colubrid snake genera indicate that confusion exists concerning parameters used to define species assemblages. The Philodryas-Alsophis generic complex is used as a model for discussion and comment is made on taxonomic categorical alternatives.

PARTITIONING OF FOOD IN A COMMUNITY OF TROPICAL FROGS. Catherine Ann Toft. University of California, Davis, California.

In the neotropical rain forest, a number of species of frogs are found in the leaf litter by day. These species partition food on the basis of food type and food size. The structure of this community has at least these components: number and equitability of species; the proportion of species that specialize on different types of prey; and the similarity in prey utilization of species that specialize on the type of prey.

The factors which determine the structure of this community will vary from place to place in the neotropics and include the predictability, abundance, and seasonality of food resources. Where the relative influences of these factors vary, communities of different structure result.

THE DYNAMICS OF WATER EXCHANGE BY EGGS OF PAINTED TURTLES (CHRYSEMYS PICTA). C. Richard Tracy, Gary C. Packard, and Mary J. Packard. Colorado State University, Fort Collins.

Water exchanges of painted turtle eggs depend upon such factors as substrate water potential, relative surface of the eggshell exposed to the nest atmosphere, hydraulic conductance of the eggshell, and conductance of the eggshell to water vapor. Eggs absorb liquid water across that portion of the eggshell in contact with the substrate, and simultaneously lose water vapor from that part of the eggshell exposed to air inside the nest chamber. Depending upon the rates of influx and efflux of water, eggs may experience increases or decreases in weight during incubation, or they may maintain a constant weight between oviposition and hatching. Water absorption by turtle eggs may have considerable adaptive significance, for hatchlings emerging from eggs absorbing and storing large quantities of water are heavier than hatchlings emerging from eggs taking up smaller quantities of water from the substrate. Additionally, water absorption equal to, or in excess of, water loss by transpiration assures that the shape of the egg will be such that sufficient space is available to accommodate the developing embryo.

Tracy, C. Richard - see Packard, M.

COLLECTION OF HIBERNATING CNEMIDOPHORUS SEXLINEATUS (LACERTILIA: TEIIDE) FROM VARIOUS PARTS OF ITS RANGE. Stanely E. Trauth. Auburn University.

A total of 776 six-lined racerunners was collected during hibernation periods extending from October, 1973, to April, 1977. Lizards were unearthed from 299 separate localities in nine states. Excavations generally were made on south- and west-facing, red clay banks along secondary highways. Animals were found to hibernate communally or singly. Communal hibernacula consisting of well-developed burrow systems were occassionally found. The "typical" microhabitat site for hibernation, which varied little throughout the portion of the range studied, is discussed.

HERPETOFAUNAL RELATIONSHIPS OF SOUTH AMERICA WITH AUSTRALIA. Michael J. Tyler. University of Adelaide.

With the sole exception of the Pygopodidae, the families comprising the modern Australian herpetofauna evolved beyond its continental borders. South America constituted the first source but, in contrast with South American/African herpetofaunal exchange, there was no direct land communication with Australia, and Antarctica constituted a substantial intermediary landmass.

From South America, Australia received the Leptodactylidae and Hylidae as totally separate entities, but conceivably simultaneously. The Leptodactylidae differentiated substantially: primarily to occupy terrestrial, fossorial and aquatic niches; secondarily to form a few scansorial animals. It is not represented by the Limnodynastinae, Myobatrachinae and Rheobatrachinae. The Hylidae exploited the arboreal and scansorial regimes, differentiating from a Neotropical hyline stock to constitute an endemic subfamily: the Nyctimystinae.

Within Australia the ancestral hylid stock may have resembled the Litoria aurea group, and at an early stage this diverged to give rise to a separate lineage lacking intercalary structures and now represented solely by the fossorial Cyclorana. The second lineage produced the scansorial, and ultimately more highly modified arboreal frogs. Within this second lineage intercalary structures have become more labile, and now include all other forms recorded in the Anura. For the systematist Cyclorana remains a problematical genus which cannot be accommodated in the Hylidae.

At the time of the onset of rapid drift of Australia from Antarctica (55-53 m.y. B.P.), Australia probably lacked snakes. (A possible exception is the large boid Wonambi known from the Pleistocene of South Australia, and with apparent affinites to Madstoia.) At that time the only lizards in Australia were the diplodactyline geckos from which the Pygopodidae evolved.

Pleurodine chelonians are restricted to the Neotropical and Australian Regions, but the Chelidae is the only modern family common to both. The current distribution of chelids in Australia is unquestionably relictual; the family occurred as far south as Tasmania in the Eocene, and in the now arid Central Australia in the Miocene. Chelid source ancestry is uncertain; the Lower Cretaceous Chelycarapookidae of Victoria is a candidate.

The depauperate nature of the Australian fauna was remedied in the Miocene. In the mid-Miocene New Guinea (the leading edge of the Australian continental plate) collided with a chain of oriental islands and accreted some of them. These islands were occupied by various ranid genera including Platymantis and by the microhylids Oreophryne and Sphenophryne. The Carettochelyidae, Scincidae, Boidae (Pythoninae), Elapidae, Agamidae, Varanidae and Typhlopidae all entered as a result of this collision - some at the time

of impact and others subsequently. The Ranidae and Scincidae had at least two invasions, and in general the sequence of arrival greatly influenced the relative success of the colonisers. Nevertheless ranids and microhylids have scarcely penetrated northern Australia. Hence the anuran fauna of Australia is almost wholly from a South American source, whereas the reptile fauna is predominantly Oriental.

VanDenbos, Gary - see Williams.

STRUCTURAL PATTERNS OF SPONTANEOUS AND EVOKED CALLS IN THE BUFO SPINULOSUS SPECIES GROUP (AMPHIBIA-BUFONIDAE). Alberto Veloso M. and Mario Penna V. Universidad de Chile.

There are two allopatric species of the genus Bufo in Central Chile (Lat. 33S). Bufo spinulosus lives in the highlands (Andes mountains) and B. chilensis in Acacia caven steppes and coastal lowlands. A third species, B. atacamensis (Lat. 28S) has a narrow distributional range and is restricted to small valleys surrounded by an extreme xeric environment. Absence of spontaneous vocal activity has been indicated as an important character in this group. This statement is not according with present observations. Bufo spinulosus during the reproductive season shows a spontaneous call in the field. The call consist in a complex signal initiated with a single pulse structure followed by a trill. The same signal is present during homosexual and heterosexual amplexus or can be artifically evoked. Bufo chilensis, a closely related species, shows a typical release call, elicited by homosexual amplexus. A second call is produced during the amplexus and differs from the release call in duration, pulse frequency and energetic parameters. There is geographic variation in the release call of B. chilensis. The northern populations exhibit different pulse frequency and modulation than southern populations. Furthermore, marginal northern populations show similar call characteristic than the geographically isolated Bufo atacamensis. Intrageneric relationships are pointed out by present call analysis. Supported by Proj. 3098. Univ. de Chile and Prog. Multinacional de Genetica, O.A.S.

THE HISTORY AND DISTRIBUTION OF AN INTRODUCED POPULATION OF LACERTA MURALIS (REPTILIA, SAURIA, LACERTIDAE), IN CINCINNATI, OHIO. Gregory O. Vigle. Cincinnati Museum of Natural History.

A sizable population of Lacerta muralis has been established in an urban area within the city limits of Cincinnati as the result of the release of two individuals in 1948. The original pair of lizards was captured in the Lake Como region of northern Italy by a young boy who brought them to Cincinnati and released them outside his home, hoping that they would reproduce. They did.

The lizards are present in large numbers on stone and concrete walls on the north valley wall and flood plain of the Ohio River. It appears that the lizards inhabit an area of approximately one by three kilometers, with the original release site being near the center of distribution. Well-traveled roads have not limited the spread of the population.

AMPHIBIAN EGGS: A NEGLECTED MICROHABITAT. Jaime Villa. Section of Neurobiology and Behavior, Cornell University.

In the past hundred years herpetologists have collected the eggs of hundreds of amphibian species and have described them (or the resulting larvae), usually viewing the eggs as a brief, transitory stage of the amphibian life cycle.

Organisms found in association with the eggs, however, have been traditionally neglected (or given only very limited attention) although they may be a very important (often adverse) factor in the amphibian's population. For many organisms--ranging from fungi and single-celled algae--amphibian egg masses are an important (and sometimes even obligatory microhabitat where developing and/or feeding takes place. Cases are presented of associations ranging from occasional commensals to parasites and predators of the embryos before or after hatching. Usually these associations are not restricted by taxonomic or geographic boundaries. On the contrary, they are likely to be found anywhere in the world where amphibians breed; work in this direction is only beginning.

GENETIC DIFFERENTIATION, ALBUMIN EVOLUTION, AND THEIR BIOGEOGRAPHIC IMPLICATIONS IN PLETHODONTID SALAMANDERS (GENUS HYDROMANTES) OF CALIFORNIA AND SOUTHERN EUROPE. David B. Wake, Linda R. Maxson, and Gloria Z. Wurst. University of California, Berkeley; University of Illinois, Urbana; University of California, Berkeley.

Genetic variation and albumin evolution were studied in the plethodontid salamander genus Hydromantes using starch-gel electrophoresis and the immunological technique microcomplement fixation. There is generally high concordance in the data from these two approaches. The three California species are relatively little differentiated, with H. shastae showing as much differentiation among various populations as occurs between the three species. The Sardinian H. genei and H. italicus (from the mainland, primarily Italy) are strongly differentiated, and form a separate but not well defined group, while the three California species form a much tighter, less differentiated group. The curious distribution of the highly derived genus and the fact that the two European species are the only members of the large family Plethodontidae in the Old World are considered in the light of the new data. Plethodontids are thought to have dispersed to present-day Europe from North America, with phylogenetic separation of the groups dating to Oligocene times. Separation of the two European species was just a little more recent. Hydromantes, like many other amphibians, has changed little at the organismal level despite great change at the level of structural genes (research supported by NSF grant BMS 74-20922).

THE EFFECTS OF TEMPERATURE ON THE REPRODUCTIVE CYCLE OF THE MALE WATER SNAKE, (NATRIX SIPEDON). Michael R. Weil and Robert D. Aldridge - St. Louis University.

The effect of various temperatures upon the male reproductive cycle of the common water snake (Natrix sipedon) was studied. Snakes were divided into five groups and kept in five different temperature regimes for ten weeks. Those kept in chambers 1-4 were maintained at 21.3, 23.3, 27.4, and 29.3°C for 8 hours per day respectively. All were kept at 20°C for the remaining 16 hours per day. Controls were kept at 20° C for the entire day.

Testicular growth appears to be positively correlated with increasing temperatures, as measured by estimated testis volumes. Additionally, increases in seminiferous tubule diameters appear to be nearly linearly related to increases in temperature. This was determined by measuring 20 seminiferous tubule diameters for each individual and averaging the results for all individuals within an environment. Interstitial cell nuclear diameters were measured in the same manner as seminiferous tubule diameters and were found to be unrelated to temperature. Spermatogenesis was measured

by approximating the number of rows of each type of meiotic cell and then assigning one type as being most prevalent. Rate of germ cell proliferation appeared to increase with increasing temperatures except in the two warmest environments where spermatogenic activity was similar.

HERPETOFAUNAL SURVEY OF THE SINAI PENINSULA (1967-1977). Yehuda L. Werner. University of Chicago, Illinois

Collections from Sinai in the Hebrew University of Jerusalem and in Tel-Aviv University, made in 1956 and since 1967, exceed 1000 specimens and 50 taxa. The author created manual locality-record maps as part of a distributional checklist of the reptiles of Israel and Sinai being prepared with J. H. Hoofien; and is examining morphological variation as part of a computerized study of geographical variation of squamates in the area Turkey-Sinai with C. Kosswig (DFG-funded).

The only amphibian found is Bufo viridis.

Of the 50-plus reptiles, 9 taxa have not previously been confirmed from Sinai; only 5 taxa do not occur in the Negev as well. Ten additional taxa occur in both Israel and Egypt: 5 probably do occur in Sinai; 5 others apparently lack suitable habitats there (including Acanthodactylus pardalis whose record had been based on an A. boskianus - courtesy H. Marx). A dozen literature records await verification and some (e.g., Agama mutabilis seem erroneous.

The interesting reptile community of N Sinai dunes includes Testudo kleinmanni (in dunes elsewhere in the region replaced by T. graeca), Stenodactylus petrii (elsewhere S. doriae), S. stenodactylus, Agama savignii (elsewhere A. pallida), Chamaeleo c. musae (C. c. recticrista), Acanthodactylus scutellatus (elsewhere A. boskianus or A. schreiberi), Eremias olivieri, Sphenopssepsoides (elsewhere Chalcides ocellatus), Scincus scincus, Lytorhynchus diadema, Spalerosophis vipera (elsewhere C. cerastes).

Ptyodactylus hasselquistii guttatus inhabits northern and central Sinai and southern mountaintops, whereas in the southern canyons P. h. cf. hasselquistii occurs.

Thus, herpetologically, Sinai turned from a poorly-known into a well-known corner of the Near-East.

PLATYSTERNON AND THE EVOLUTION OF CHELYDRID TURTLES. K. N. Whetstone. University of Kansas, Lawrence.

Gaffney (1975) placed the Asiatic genus Platysternon in the Chelydridae on the basis of a presumed sister group relationship to Macroclemys. Additional specimens of the Miocene Macroclemys schmidti indicate that some of the characters hypothesized by Gaffney to be synapomorphies actually represent convergences. Also, Platysternon lacks the cruciform plastron, narrow epiplastra, "T" shaped entoplastron, serrated carapacial margin, and long costiform process on the nuchal bone which are found in Chelydra and Macroclemys. If Platysternon is a chelydrid, loss of these characters must be interpreted as evolutionary reversals. No hypothesis of reversal for these characters is necessary if Platysternon represents the sister group of the Emydinae (sensu McDowell). Platysternon shares at least one presumed synapomorphy with emydines and testudinids, the presence of two biconvex vertebrae in the neck. Platysternon also has a double articulation between the 5th and 6th cervicals, a character otherwise unique to the Emydinae.

The oldest known chelydrid turtle is a new genus from the Upper Cretaceous Hell Creek Formation of Montana. This turtle is distinguished from other known chelydrids by a suite of plesiomorphic characters which support Gaffney's theory of independent shell reduction for chelydrids and toxochelyids.

ANURAN SUCCESSION AT TEMPORARY PONDS IN A POST OAK SAVANNA REGION. John A. Wiest, Jr. Texas A&M University.

Reproductive strategies of anurans utilizing temporary ponds in a Texas post oak savanna region were studied during an abnormally wet year, September 1972 through September 1973. Anuran succession was documented and correlated with varying environmental conditions. The overriding causes of variation in anuran reproductive patterns were due to fluctuations in air and water temperatures, rainfall, and possibly humidity. The anuran species in the study area were separated spatially and temporally. Calling, breeding, and larval periods for nine species were documented. The vocalization strategy, based on the first evening when calling was heard for each species, was as follows: Rana sphenocephala, vocalized first, followed by Pseudacris streckeri, Pseudacris triseriata, Pseudacris clarki, Scaphiopus holbrooki, Acris crepitans, Hyla versicolor, Bufo valliceps, and Gastrophryne olivacea. Males of each species initiated the calling period, and the presence of adult females determined the breeding period. Calling activity was not always a good predictor of the presence of larvae for a particular species, and each species was present as larvae over a different time span. For most anurans there was a larval bloom in April and May, and these months corresponded to the time of the year associated with the most rainfall. Because of the drying tendencies of temporary ponds, there is an adaptive advantage for most larvae to be in the ponds in spring months.

EFFECT OF THYROID HORMONE ON HEPATIC CELL PROLIFERATION AND TURNOVER IN THE BULLFROG TADPOLE. James Williams, Wahleah Baker, Robert Phillips and Gary VanDenbos. Northeastern Oklahoma State University, Tahlequah, Oklahoma.

The precocious initiation of a number of biochemical changes associated with metamorphosis have been documented using thyroid hormones(TH). Reports describing the biochemical transformation and ultrastructural reorganization of the liver in Rana catesbeiana tadpoles during metamorphosis fall into two conflicting categories. One group assumes the metamorphic transition occurs in a population of cells existing before the onset of metamorphosis. Another assumes the hepatic transition occurs in a new population of cells, cells produced in response to early metamorphic signals. The audioradiographic analysis of the incorporation of ^{3}H thymidine into liver cells as a function of TH was used as an indicator of mitotic activity. These studies suggest a TH mediated increase in the fixation of ^{3}H thymidine in particular hepatic cells while the labeling kinetics of ^{125}Id-Urd suggest the thyroid hormone induced metamorphic transitions of the liver can be thought of as occurring in an essentially fixed population of cells. HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of Herpetological Review in 1967 (Corson Hirschfeld, Editor):

> "Herpetological Review incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the Review will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Now in its tenth year, Herpetological Review remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the Journal of Herpetology -- see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Authors are urged to write the editors before submitting feature-length articles. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles are desired. Submissions should be black-and-white, 8 X 10, glossy prints, and should be accompanied by a descriptive caption and exposure data. The name and address of the contributor should be taped or penciled on the back of each print. Please DO NOT send photographs before corresponding with the editors about them. Return of unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions can be supplied if desired. Contributors will receive ordering information prior to publication of their material. Herpetological Review will accept commercial advertising. Rates and copy information are available from the editors.

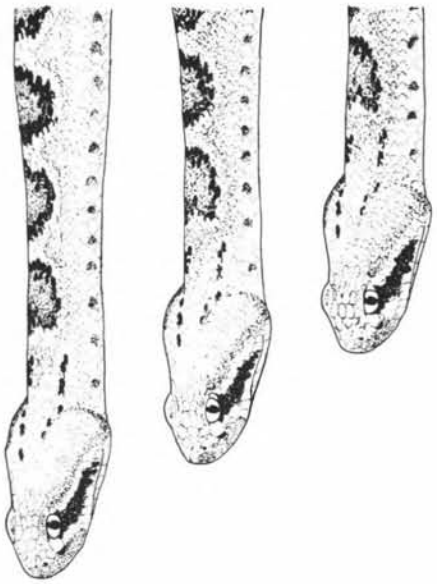
SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the Journal of Herpetology (four issues per year), Herpetological Review (four issues per year), Herpetological Circulars, and several Facsimile Reprints in Herpetology. Members may purchase other Society publications at reduced rates.



Annual Dues

Student Member	$ 8.00
Regular Member	10.00
Sustaining Member	15.00
Contributing Member	20.00
Institutional Subscription	20.00

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of the SSAR. For information regarding SSAR membership, write to:

Annual Meeting News

HERPETOLOGY AT THE UNIVERSITY OF KANSAS

One of the first actions of the Kansas Territorial Legislature was the creation of an institution of higher learning called the University of Kansas Territory. In September 1866 the first class of 29 men and 26 women entered The University of Kansas located on the hill "Mount Oread" on the outskirts of the village of Lawrence. From that small start The University of Kansas has grown to a comprehensive institution of higher learning. The main campus, where more than 22,000 students now attend classes, is situated in the midst of Lawrence, a thriving community of more than 50,000 residents in the forested hills of eastern Kansas midway between Kansas City and Topeka.

Biological Sciences have had a long and illustrious history at The University of Kansas. Indeed in 1864 the Kansas Territorial Legislature authorized the establishment of a "Cabinet of Natural History." One of the first professors at the university, Francis Huntington Snow, was a renowned entomologist who became Chancellor of the university (1890-1901) and established the nucleus of insect collections upon which the Snow Entomological Museum was founded; the museum currently houses more than 2.5 million specimens. During Snow's chancellorship, several famous biologists joined the faculty; among them were Lewis Lindsay Dyche, Clarence E. McClung, and Samuel W. Williston. McClung initiated the comparative study of animal chromosomes. Dyche and Williston were responsible for building the collections of recent and fossil vertebrates, respectively, and in 1900 the state legislature appropriated funds for the construction of the Museum of Natural History, which honors Dyche's memory by bearing his name--Dyche Hall. A large wing was added to the museum in 1963.

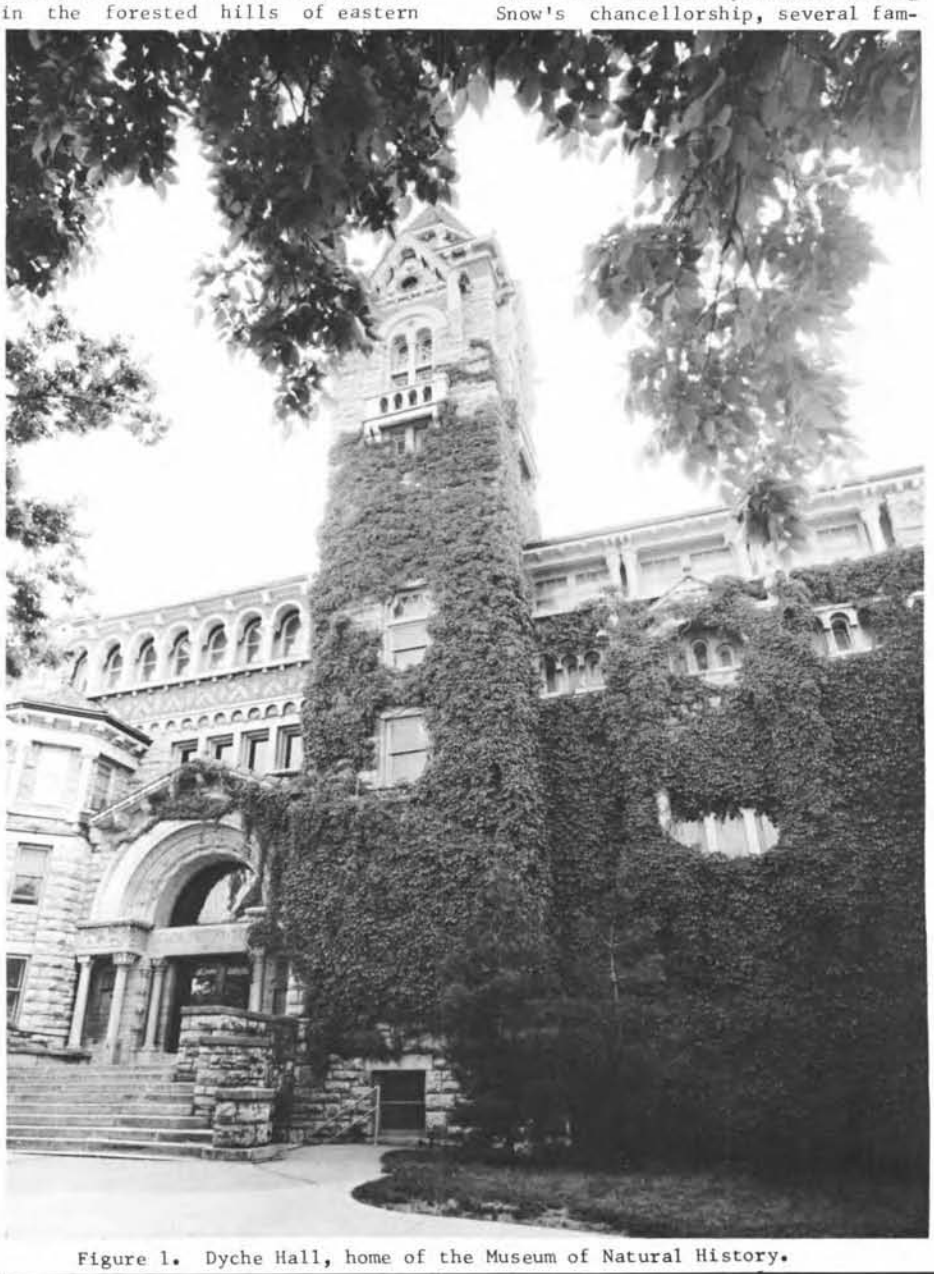

Figure 1. Dyche Hall, home of the Museum of Natural History.

The early (1900-1920) herpetological collections of the Museum of Natural History were obtained by field parties working under the auspices of the State Biological Survey. However, commencing in the 1920's, Dr. Edward H. Taylor and his students expanded collecting efforts to adjacent states, southeastern United States and eventually to Mexico. Thus, as the first curator of the herpetological collections, Taylor influenced their growth and scope, and there were more than 40,000 specimens at the time of his retirement as curator in 1954. Taylor had an active group of graduate students, notable among whom were David M. Dunkle, Claude W. Hibbard, Hobart M. Smith, Wilmer W. Tanner, and Joseph A. Tihen. In the 1950's John M. Legler and Robert G. Webb completed their Ph.D. work under the guidance of Henry S. Fitch. John M. Legler was an interim curator of herpetology from 1954 to 1959, during which time the collections increased to 51,000 specimens, the increment representing the collections primarily from Costa Rica made by Edward H. Taylor.

William E. Duellman became Curator of Herpetology in 1959 and initiated active collecting and research programs in Mexico, Central America and South America. With the enthusiastic assistance of numerous graduate students and Linda Trueb, Adjunct Curator of Herpetology, the Division of Herpetology became one of the most active and productive divisions in the Museum of Natural History. The collections grew to more than 175,000 specimens (the last 15,000 having been computer-catalogued); including more than 300 primary types and 7,500 skeletons. Associated with the collections are more than 6,000 color transparencies of amphibians and reptiles, 1350 tape recordings of anuran calls, and smaller holdings of chromosome preparations and serial sections of heads of anurans. The herpetological library contains nearly 1000 bound

volumes and more than 6000 reprints. Facilities in the Museum of Natural History include histological, karyological, and bioacoustical laboratories, plus dark room and computer facilities.

Other centers of herpetological activity at The University of Kansas include the experimental laboratories in Haworth Hall, the State Biological Survey, and the Natural History Reservation. The laboratories in Haworth Hall are under the direction of Harvey B. Lillywhite. Facilities there include controlled environmental chambers and rooms, physiological instrumentation, gas analyzer, temperature recorders, and instruments for measuring micrometeorological variables.

The State Biological Survey of Kansas is required by Kansas Statute to determine the distribution, abundance, and population characteristics of native plants and animals of the state and to publish reports of the findings. Jan Caldwell, Assistant Director of the State Biological Survey, directs investigations on vertebrates and collaborates with Joseph T. Collins in documenting the distribution of amphibians and reptiles in Kansas.

The University of Kansas acquired the Natural History Reservation in 1947. This 590 acre tract is 7 miles north-northeast of the campus. The reservation includes flat uplands, rocky slopes, and bottom land; the tract is used by classes in ecology and natural history and for a variety of research projects. Many publications have dealt with diverse aspects of the soils, meteorology, and biota of the area. Long term studies on the herpetofauna (27 reptiles and 10 amphibians) have dealt with food habits, spatial relationships, temperature relationships and reproductive cycles. Many of the common species have been subjects of autecological studies. Henry S. Fitch has been the resident naturalist and superintendent of the reservation since 1948.

Present faculty members, departmental affiliations, and herpetological research interests are:

Jan Caldwell, State Biological Survey and Department of Systematics and Ecology--1) Anti-predator mechanisms in tadpoles; 2) Demography and population structure of amphibians; and 3) Hybridization and call discrimination in the Rana pipiens complex in Kansas.

William E. Duellman, Museum of Natural History and Department of Systematics and Ecology--1) Systematics of Neotropical hylid and centrolenid frogs; 2) Evolution of egg-brooding hylid frogs; 3) Biogeography of the Andean herpetofauna; 4) The amphibians and reptiles of Panama; and 5) Community diversity in tropical herpetofaunas.

Henry S. Fitch, Department of Systematics and Ecology--1) Comparison of reproductive strategies of tropical and temperate reptiles; 2) Ecology and evolution of Anolis in Mexico and Central America; 3) Ecology and conservation of Iguana and Ctenosaura in Central America; and 4) Natural history of the glass lizard, Ophisaurus attenuatus.

Harvey B. Lillywhite, Departments of Physiology and Cell Biology and Systematics and Ecology--1) Blood pressure regulation in snakes; 2) Physiological ecology of amphibians with reference to heat and water exchanges; 3) Functional correlates of integumental structure in reptiles; and 4) Small animal responses to fire and habitat disturbance in Southern California chaparral.

Edward H. Taylor, Museum of Natural History and Department of Systematics and Ecology (emeritus)--Systematics and morphology of caecilians.

Linda Trueb, Department of Systematics and Ecology and Association of Systematics Collections--1) Evolutionary osteology of anurans; 2) Systematics of leptodactylid frogs, genus Telmatobius; 3) Osteology of hylid frogs, genus Gastrotheca; and 4) Evolutionary relationships of Neotropical montane bufonids.

Other personnel engaged in herpetological research include Joseph T. Collins, Museum of Natural History--Studies on the herpetofaunas of Kansas and Kentucky; Stephen R. Edwards, Association of Systematics Collections--Systematics of dendrobatid frogs, genus Colostethus; and George R. Pisani, Division of Biological Sciences--Systematics of the snakes of the genus Virginia and aspects of snake reproduction.

Four non-resident Research Associates in the Division of Herpetology of the Museum of Natural History contribute to the research programs at the university; these are Werner C.A. Bokermann, Sao Paulo, Brasil; John D. Lynch, Lincoln, Nebraska; Michael J. Tyler, Adelaide, Australia; and Alberto Veloso M., Santiago, Chile.

A very active graduate program in herpetology at The University of Kansas has resulted in 15 students completing the Ph.D. in the past decade--Ray D. Burkett, Jan Caldwell, Donald R. Clark, Jr., Martha L. Crump, Arthur C. Echternacht, Stephen R. Edwards, Russell J. Hall, Thomas H. Fritts, John D. Lynch, Richard R. Montanucci, Charles W. Myers, Michael V. Plummer, Gerald T. Regan, A. Kenneth Smith, and Linda Trueb.

A diversity of research in herpetology is reflected among the dissertation topics of the 18 students currently pursuing graduate degrees at The University of Kansas: Marshall L. Anderson (Ph.D.) --Morphology of anuran hands and feet; Thomas J. Berger (Ph.D.)--Analysis of tropical tadpole communities; David C. Cannatella (Ms.)--Evolutionary biology of phyllomedusine frogs; Eleanor J. Daly (Ph.D.)--Dissorophids and the evolution of the lissamphibia; Geoffrey Friedman (Ms.)--Biochemical adaptations in temporary muscle anoxia in anurans; Richard L. Lattis (Ph.D.)--Responses to micro-climates by small snakes; Julian C. Lee (Ph.D). -- Eco-biogeography of the herpetofauna of the Yucatan Penin-

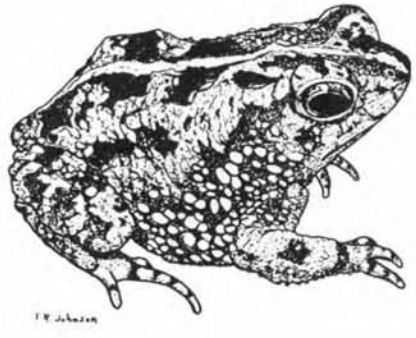

Figure 2. Kansas Union, site of sessions of the 1977 annual meetings.

sula; Juan R. Leon (Ph.D.) --Reproductive strategies of anurans in a seasonally wet tropical community; Luis Malaret (Ph.D.) -- Geographic variation in reproduction of collared lizards; Jaime E. Pefaur (Ph.D.) --Species diversity in the Lomas of southern Peru; Gregory K. Pregill (Ph.D.) -- Pleistocene herpetofaunas of the Greater Antilles; Rebecca A. Pyles (Ms.)--Anuran osteology: interspecific variations; Johnna M. Roberts (Ph.D.)--Structure and function of reptilian epidermis in relation to cutaneous water loss; Alan H. Savitzky (Ph.D.) -- Intergeneric relationships of xenodontine snakes; Terry D. Schwaner (Ph.D.) --Evolutionary ecology and biogeography of Samoan lizards; Robert C. Waltner (Ph.D.)--Effect of altitude on ecology of Himalayan Agama; Kenneth N. Whetstone (Ms.)--Early evolutionary history of chelydrid turtles; Bernard Willard (Ms.)--Phenetic analysis of Leptodeira.

Personnel at The University of Kansas are active in biological organizations. Jan Caldwell is the Past-President of the Kansas Herpetological Society. Joseph T. Collins is President-Elect of the Society for the Study of Amphibians and Reptiles and with George R. Pisani edits Herpetological Review. Pisani is also editor of Herpetological Circulars. William E. Duellman is the President of the Herpetologists' League and a Council Member of the Society of Systematic Zoology. Stephen R. Edwards is Secretary of the Society for the Study of Amphibians and Reptiles and, with Linda Trueb, manages the Secretariat of the Association of Systematics Collections, a consortium of 65 institutions housing systematics collections and 10 affiliate profesional societies, including the American Society of Ichthyologists and Herpetologists, the Herpetologists' League, and the Society for the Study of Amphibians and Reptiles.

WILLIAM E. DUELLMAN, Museum of Natural History and Department of Systematics and Ecology, The University of Kansas, Lawrence, Kansas 66045 U.S.A. ●

REPRODUCTION OF THE CHINESE RED SNAKE, DINODON RUFOZONATUM (CANTOR) IN CAPTIVITY

Two clutches of eggs from Dinodon rufozonatum have been hatched at the Fort Worth Zoological Park since 1973. One report in the literature gives a clutch size of 11 eggs for this species, and mentions that a second female contained eight developed and three undeveloped eggs (Pope, 1929). Two specimens at the American Museum of Natural History were reported to be embryos "on the point of hatching." The two embryos, 232 and 244 mm in length, came from eggs of 33 and 38 mm in length respectively (Pope, 1935).

Since 1973, one adult male and two adult female Dinodon rufozonatum have been housed on exhibit in a two foot fiberglas enclosure (Hulsey, 1973). They are provided with a gravel substrate, water bowl, and the cage is decorated with plastic plants, rocks, and a piece of bark. Temperature in the enclosure varies from approximately 23 to 32 C. Adults feed on two to three adult mice per week.

The snakes were received at the zoo on 3 May 1973. The first clutch was laid on 13 July 1973 and consisted of three eggs. The eggs ranged from 23 to 33 mm ($\bar{x}$ = 31 mm) in length, and had a diameter of 15 to 16 mm ($\bar{x}$ = 15.3 mm). Their weights ranged from 4.2 to 5.0 g ($\bar{x}$ = 4.7 g). Two young hatched after an incubation period of 49 da August 1973. Each young measured 240 mm in length, and weighed 4.3 and 3.7 g ($\bar{x}$ = 4.0 g).

Breeding activity was observed on 22 June 1974 and again on 21 November 1974, but no eggs were laid that year. Breeding activity was next recorded on 26 February 1976. The gravid female was removed from exhibit and provided with a bowl containing a damp mixture of sphagum moss and vermiculite for egg deposition. On 20 April 1976, seven white, leathery eggs were laid. The eggs were placed in a 5 gallon aquarium with an equal mixture of vermiculite and water (Tryon, 1975). The eggs ranged from 32 to 47 mm ($\bar{x}$ = 38.7 mm) in length and from 15 to 17 mm ($\bar{x}$ = 15.3 mm) in diameter. Weight ranged from 5.2 to 8.3 g ($\bar{x}$ = 6.9 g). Temperature during incubation fluctuated between 29 and 35 C. The total length of the hatchlings was from 243 to 265 mm ($\bar{x}$ = 254.8 mm). Hatchlings were measured using the squeeze box technique (Quinn and Jones, 1974). Their weight ranged from 4.6 to 7.4 g ($\bar{x}$ = 6.2 g).

Hatchlings from both the 1973 and the 1976 clutches had the same pattern as the adults, but the colors were much more vivid. All were fed on newborn mice with the exception of one individual from the 1976 clutch which fed on Virginia.

A gravid female was removed from exhibit on 3 March 1977 and provided with a nesting box containing damp sphagnum moss. On 22 March 1977, 12 white, non-adjering eggs were deposited in the medium provided. The eggs range from 29 to 39 mm ($\bar{x}$ = 33.4 mm) in length, 16 to 18 mm ($\bar{x}$ = 16.8 mm) in diameter, and 5.3 to 7.1 g ($\bar{x}$ = 6.2 g) in weight. The eggs are being incubated as described above.

The data reported here was collected and recorded by the staff of the Herpetarium at the Fort Worth Zoological Park.

DEPOSITION OF PARATYPES OF EURYCEA JUNALUSKA

Paratypes of Eurycea junaluska listed by Sever, Dundee, and Sullivan (1976) as being in the D.M. Sever collection (DMS) have been deposited in the Museum of Vertebrate Zoology, University of California (MVZ) and in the Museum of Zoology, the University of Michigan (UMMZ). Collection numbers for these specimens are:

DMS 1865.....MVZ 128276
DMS 1866.....MVZ 128277
DMS 2077.....UMMZ 142790
DMS 2144.....UMMZ 142791
DMS 2128-2138.....UMMZ 142792-142802

A MASSACHUSETTS HIBERNATION SITE OF THE RED-BACKED SALAMANDER, PLETHODON CINEREUS

During February 1976, 87 hibernating Plethodon cinereus (Green) were found incidental to the excavation of tree stumps in Plymouth County, Massachusetts.

Four to twelve stumps of each of the following recently cut trees were removed from a one-quarter acre site: White oaks, Quercus alba; Red maple, Acer rubrum; Sassafras, Sassafras albidum; Sour-gum, Nyssa sylvatica; and White pine, Pinus strobus.

An excellent opportunity for detailed observation was possible since excavation was done with a hand operated portable winch and a shovel. Bishop (1941) in his natural history review of this species mentions no hibernation sites. Grizzell (1949) reports a single specimen from an excavated woodchuck den. Cooper (1956) records an aquatic hibernation and Caldwell and Jones (1973) and Caldwell (1975) report two winter congregations in ant mounds.

Eighty-six of the salamanders were collected from beneath the stumps of six recently cut white oaks. They occurred by count as: 3, 4, 11, 12, 21 and 35. All were taken from the B horizon (subsoil) at depths from 30-36 inches. The animals were usually found individually in partially rotted-out root channels. The favorite sites were still lined with root cork with some moist decomposing root tissue still present. The soil temperature during excavation was from 5-9 C. All of the salamanders were active immediately after discovery. A stomach analysis of nine individuals showed six to be empty; the other three contained fragments of Carpenter ants, Camponotus sp.

The lone individual not collected from white oak root systems was collected beneath the large tap root of a sour-gum. Two American toads, Bufo americanus, were also collected beneath a sour-gum. No other reptiles or amphibians were noted.

It seems apparent that the decaying root system of dead white oaks is a preferred hibernation habitat for the red backed salamander in woodlots of southeastern Massachusetts.

Jeffrey G. Hoff and James G. Hoff, Jr. assisted with the excavation work.

WINTER COLLECTION OF CNEMIDOPHORUS SEXLINEATUS EGGS FROM ARKANSAS

The overwintering of incubating eggs or fully-developed young in the egg, termed embryonic hibernation (Porter, 1972), has been reported for few reptiles; e.g., Sphenodon punctatus (Sharell, 1966), Chelydra serpentina serpentina (Oliver, 1955; Porter, 1972), Clemmys insculpta and Chrysemys picta (Nichols, 1933; Oliver, 1955). Bellairs (1970) indicated that gestating embryos, following an autumn mating by parents, may overwinter within their hibernating mother; however, no supportive evidence was given. Embryonic hibernation is usually a direct result of cold early autumn temperatures which retard the hatching or embryological development of young (Oliver, 1955). Jameson (1974) suggested that montane populations of Sceloporus graciosus lay eggs which overwinter and hatch the following spring. The following is the first documented evidence known to this author of overwintering of eggs for any North American lizard.

While searching for hibernating C. sexlineatus on December 28, 1974, on top of Judea Mountain (609 m), 6.5 km S Jasper, Newton Co., Arkansas, I unearthed two racerunner eggs. The nest was found on a well-drained, red clay embankment of a moderate, southwest-facing slope. The eggs were at a depth of approximately 1 dm in an oval chamber adjacent to the hibernation burrow of an adult female racerunner. Unfortunately, one egg was destroyed during excavation. The other, measuring 18 mm x 11 mm contained a healthy-looking, and, based on my past experience, viable embryo (27 mm SVL; 50 mm tail length) and a small amount of yolk. The distinctive color pattern was evident, indicating that embryonic development was essentially complete (Brimley, 1903).

C. sexlineatus (adults, juveniles, and hatchlings) hibernate in burrows that are situated in close proximity to nesting cavities (Trauth, 1974). I have uncovered late season clutches along with hibernating animals from Washington and Independence Counties (Ozark Mountains) from late August to mid-September in 1973 and 1975, and several clutches were taken during September, 1974, from Dallas Co. (Coastal Plain). However, excavation of dens and collection of over 500 hibernating racerunners from all regions of the state resulted in only these two eggs being taken during winter conditions (mean January temperature for Newton Co. - 2.7 C). Survival of C. sexlineatus embryos at temperatures near freezing appears to be similar to results experimentally obtained for Eumeces fasciatus and E. obsoletus eggs (Fitch, 1964; Fitch and Fitch, 1967). If we assume that overwintering eggs are viable, the spring hatchlings (late April-early May) in Arkansas would probably fail to become sexually mature their first summer and would not contribute to the reproductive effort like most first-year animals of this species.

I wish to thank Drs. J.L. Dobie, G.W. Folkerts, and R.H. Mount for their comments on this manuscript.

RECORD EGG CLUTCHES FOR CLEMMYS INSCULPTA

Ernst and Barbour (1972) record the maximum clutch size for the Wood Turtle (Clemmys insculpta) as 12. Gammons' (1871) account of a female laying 18 eggs was rejected by Carr (1952). On 13 June 1976, I collected a clutch of 18 eggs of this species during an on-going study of a marked population of Wood Turtles in Schoolcraft County, Michigan. The eggs were tightly packed in a globular cluster; the top egg was approximately 70 mm below the surface. The structure of the nest left little doubt that it was the work of a single female turtle. All but two of the eggs were of normal size for the species; none of the eggs were fertile. The normal-sized eggs ranged in length from 33 to 36 mm (mean = 34 mm). The two abnormal eggs were both 30 mm in length, and irregular in shape.

Previously, two clutches of 13 eggs each were collected in the study area on 19 June 1974 and 24 June 1975. On the former date, the nesting process was observed; the nesting turtle proved larger than average for a female of this population (carapace length = 194 mm). All eggs from these two clutches proved fertile and hatched successfully in the laboratory. The possible existence of a direct relationship between size of the female and brood or clutch size receives frequent mention in the literature, but the relationship between egg fertility and clutch size appears to be unknown at present.

I would like to thank Dr. J. Alan Holman for offering valuable suggestions during preparation of this manuscript.

Herpetological Husbandry

REPRODUCTION IN CAPTIVE LOWER CALIFORNIA RATTLESNAKES, CROTALUS ENYO ENYO (COPE)

There is little literature data concerning reproduction of the Lower California rattlesnake, Crotalus enyo enyo, a form occurring from El Marmol south to Cape San Lucas, Baja California, Mexico. Klauber (1937, 1972) estimated the average size at birth as 225 mm, and gave brood sizes of six and nine. The present report gives details of successful reproduction in captive C. e. enyo in two separate collections with notes on the young from four litters.

MATERIALS AND METHODS.-- A young adult female C. e. enyo (total length 714 mm, weight 447 g, postpartum) received 6 December 1972 and a young adult male (total length 662 mm, weight 332 g) received 20 October 1974, were placed on exhibit at the Fort Worth Zoological Park in a 61 cm fiberglas cage (Hulsey, 1973). The cage was decorated with several rocks and a small live cactus, arranged to provide hiding areas. Pea gravel comprised the substrate. Water was always available but the cage remained dry. Artificial lighting was provided between 0800 h and 1730 h daily with a 30 w fluorescent tube (Vitalite). Additionally, clear skylights above the cage provided a natural photoperiod for the Fort Worth area. Temperature fluctuated daily from approximately 23° C to 32° C in summer and from approximately 22° C to 28° C in the winter. Each snake fed at weekly intervals on one 15-20 g mouse.

The conditions under which the specimens in the collection of the second author were kept were somewhat different from those given above. The two females (CWR specimens A, B) were born in captivity during the first week in August 1972 and were acquired before their first shed. They were fed newborn mice every five days for the first two months and then were fed weekly one mouse of appropriate size until they reached adult size which was about 18 months of age. At that time biweekly feeding was begun. The snakes were housed in 38 liter reptile tanks with newspaper as substrate and a few large flat rocks for hiding areas. The daytime temperature was generally kept between 27° C and 30° C throughout the year, although summer temperatures were occasionally as high as 33° C. Night temperatures were usually between 22° C and 25° C. No attempt was made to maintain a regular photoperiod.

The male specimen was received in mid-1974 and was kept under the same conditions as the females. Prior to this it had been maintained in a large container with heat lamps focused at particular spots which provided an opportunity for thermoregulation.

OBSERVATIONS.-- The first observed reproductive activity in the FWZP specimens was on 1 June 1976, when the female began shedding her skin. The male was courting with a series of alternating tongue flicks and head jerks along the female's dorsum. Courting activity and attempted copulation continued throughout the day and then again on 2 June 1976 without observed copulation. At 0800 h, 3 June, copulation was in effect and continued two hours. No further reproductive activity was noted until 30 August 1976 when the female again shed. Although the male attempted to stimulate the female through courting gestures, she remained coiled and appeared unreceptive. On 1 September 1976, the female was isolated off exhibit. She continued feeding weekly, and her weight appeared to increase dramatically after 1 October.

At 0800 h, 21 November 1976, 171 days after observed mating, parturition had begun and five young were present. One appeared newborn and was coiled in a thin, watery fluid. At 1830 h the female began contracting posteriorly and a juvenile's head appeared through her cloacal opening. Further contractions caused the juvenile to crawl completely from the cloaca. Fluid, but no actual membrane, could be detected. At 0930 h the last juvenile emerged as described above and had no detectable membrane. Klauber (1972) found egg teeth in embryos of this species. None was noted in this brood.

The juveniles were measured using the squeeze box technique (Quinn and Jones, 1974) and weighed on a triple beam balance on 22 November 1976. Total length varied from 214 mm to 235 mm (mean 223.4 mm) and weight varied from 9.7 g to 11.1 g (mean 10.2 g). Mean total length of the brood was 31.2 percent of the female parent's total length. Sex was determined by percentage of tail length to total length. The brood consisted of two males and five females. Percentage of tail length to total length in the two male snakes was 8.5 and 9.8 (mean 9.1) and in the five female snakes it was 5.0 to 6.8 (mean 5.9). Subcaudal counts for the males were 22 and 24 (mean 23) and ranged from 18 to 20 (mean 19.5) for the females. Coloration and pattern closely resembled that of adult snakes (Figs. 1 and 2).

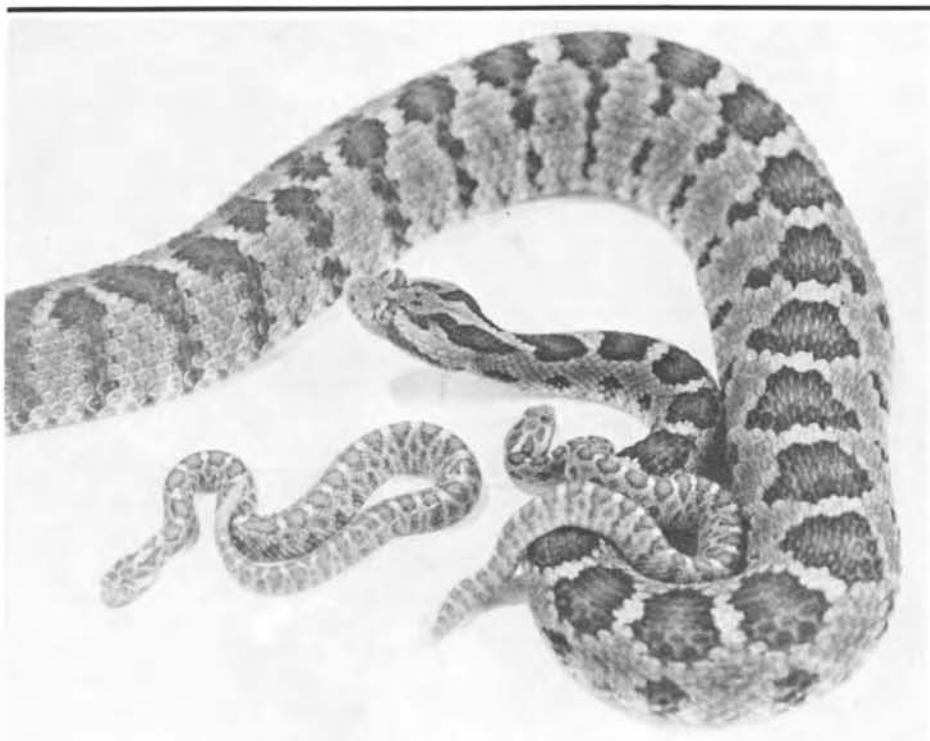

Figure 1. Adult female and two juvenile C.e. enyo several hours after birth (FWZP). Note the light colored tails of the juveniles.

The juveniles shed for the first time ten and eleven days after birth. All readily accepted newborn mice, and would strike and hold on until all movement ceased in the food item, a trait also observed in the adult snakes.

The two females in the second author's collection were placed with the adult male soon after it was acquired and the snakes were left together for a few weeks, during which the copulations were observed. Because of this, the dates given for copulation represent the last observed breeding. Female A was observed copulating with the male on 16 November 1974. Her age at that time was 27 months. On 11 May 1975, 176 days after mating, she gave birth to a litter of five which were all males. Although measurements were not recorded, the subcaudal counts of these five specimens were 24, 25, 25, 26, 27 (mean 25.4). After the young snakes had shed for the first time, they were tested for response to chemical cues from prey organisms (Burghardt, 1969). Although these snakes showed no significant behavioral differences when presented with olfactory stimuli from prey organisms or water (Chiszar and Radcliffe, in press), they immediately struck and ate newborn mice at the conclusion of the experiment.

Female A was observed mating 27 June 1975 and gave birth to a second litter of six on 21 April 1976 after a period of 299 days. It is possible that sperm retention and delayed fertilization were the causes of this extended period of time. The litter was comprised of three males, two females, and one specimen whose sex was not determined. The subcaudal scale counts on the five specimens sexed were 21 and 21 for the females and 23, 24, 26 (mean 24.3) for the males. Two were dead at birth and one died without feeding. Measurements were not recorded for this litter.

Female B was observed mating on three separate occasions. The first two occasions, 26 September 1974 and 5 July 1975, may not have resulted in fertilization. The last observed copulation was 3 August 1975. On 1 April 1976 she gave birth to a litter of two young after a period of 242 days. The birth of both snakes was witnessed (CWR) and both were in well-formed membranes from which they escaped with some struggling seven and fifteen minutes after birth respectively. The young were both males and had subcaudal counts of 24 and 26. Lengths and weights were not recorded.

Figure 2. Newborn C. e. enyo several minutes after birth (FWZP). Photo by John E. Simmons.

Lowe and Norris (1954) report four other crotalids within the range of C. enyo on the Baja mainland. These are C. ruber ruber and C. viridis helleri to the north, and C. mitchelli mitchelli and C. ruber lucasensis to the south. Although reproductive data is scant on any variety of crotalid from Baja, Klauber (1972) reported that C. r. ruber and C. viridis helleri from southern California undoubtedly mate in the spring and produce broods in the fall after an average gestation period of five months, and that this may be a few days less in the warmer areas.

Although copulation and parturition dates presented in this report are scattered, it is probable that C. e. enyo is a spring breeder in the wild but does not reproduce correspondingly in captivity regardless of conditions, as has been attributed to some reptiles (Fitch, 1970). The senior author received three apparently recently born, wild caught specimens of C. enyo furvus from a collector in October, 1974. Although measurements were not recorded, these specimens retained obvious umbilical scars and possessed only the pre-button rattle segment. In addition, it is possible that because a natural photoperiod (for Fort Worth, Texas) was available to the FWZP specimens and none to the CWR specimens, the record of 3 June to 21 November (171 days) more nearly approximates what might be expected in the wild.

ACKNOWLEDGMENTS.-- We wish to thank the staff of the Department of Herpetology, Fort Worth Zoological Park, especially Terry G. Hulsey and David B. Heckard who cared for the adult snakes in that institution. We are also indepted to Dr. David Chiszar for loaning the adult male to the second author. Upon their death, the adult and some juvenile specimens at FWZP will be placed in the collection of the University of Texas at Arlington.

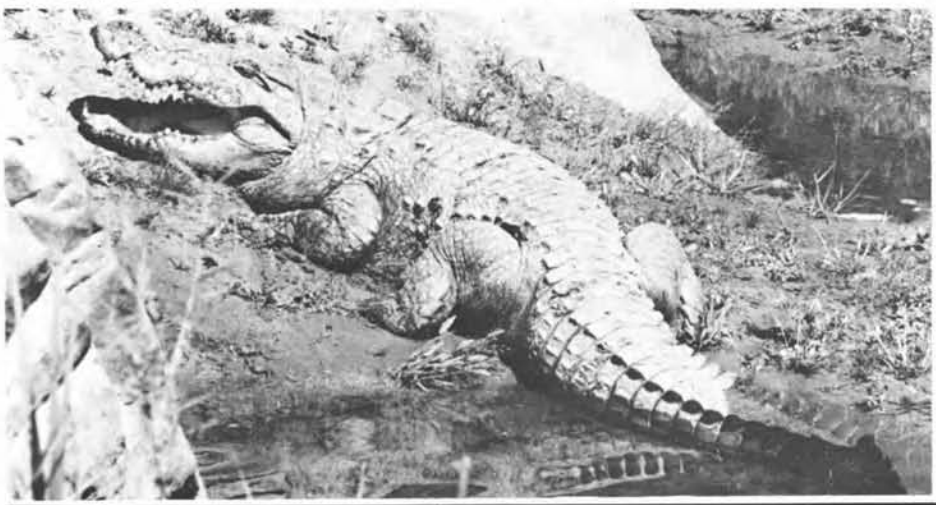
Conservation



MADRAS CROCODILE BANK TRUST

The three species of India's crocodiles are seriously threatened with extinction. The freshwater Mugger (only about 220 left in Tamil Nadu), coastal Estuarine Crocodile (less than 200 on mainland India), and the Gharial of North India (only 200 on the sub-continental) will not survive unless strong and urgent measures are taken. It is most important to avoid this as they have important roles to perform in the ecology of India. One instance of their usefulness is that they feed on big predatory fish which in turn prey on the young of commercially valuable species. Thus, they are actually helpful to fisheries and do not in fact deplete fish populations as popularly believed. However, these massive reptilian remnants of the Mesozoic age are in trouble. They have been killed extensively for their skins, and their habitats have been destroyed to make room for our exploding population with the result that few crocodiles remain in India and few places remain for them to live.

The Madras Crocodile Bank Trust, a joint project of the Madras Snake Park Trust and World Wildlife Fund India will breed and rear crocodiles for conservation. The World Wildlife Fund has given Rs. 42,000/- in grants to the Madras Crocodile Bank. Most of the balance of development costs has been raised by the Madras Snake Park Trust. Resultant offspring will be offered to the State Government for re-stocking wild habitat if a guarantee is given that these will be protected. This is a vital step towards the rehabilitation of crocodiles in India.

The aims of the Madras Crocodile Bank Trust are 1) breeding and rearing crocodiles for release in the wild; 2) encouraging and stimulating research on crocodiles, the problems and economics of their survival; and 3) public education on crocodiles, their natural history and conservation.

Romulus Whitaker is the Director of the Madras Crocodile Bank Trust and A.N. Jagannatha Rao the Honorary Secretary. Other Trustees include the Wildlife Warden (Madras) and the Deputy Director (Tourism) of Tamil Nadu. Mr. Allen Vaughn of Mayabandar, Andamans and Mr. S. Bhaskar of Madras and many others have helped the project become a reality and the people of Vadanemmeli have accepted the crocodile farm in their village as their own. The Crocodile Bank will be open to public visitation. ●

RESPONSE TO LAZELL'S LETTER ON ALLIGATORS

30 March 1977

My attention was recently called to a letter written by Dr. James D. Lazell that appeared in the September 1976 issue of Herpetological Review and referred to the National Audubon Society's alligator re-stocking program conducted in 1974 and 1975. The project involved the relocating of approximately 1,500 alligators from areas in Louisiana which supported high populations to areas in Alabama and Mississippi which were void of viable alligator populations. The program was completed as previously indicated in 1975 and was considered by all participants highly successful. While I see little need to address the merits of the program in this letter, I do feel that a response is essential to a couple of erroneous assumptions made by Dr. Lazell.

First, the National Audubon Society's joint scientific staff was not established to make decisions on all activities which the Society engages in but was established to coordinate activities in areas of mutual interest. We have not heard previously from Dr. Lazell on this well-publicized project, although all interested parties nation-wide were invited to comment on the proposal. There was only one party who raised any question about the program, and once provided clarification on the methods involved, no further questions were raised. Therefore, Dr. Lazell should not feel that he had any connection with the project although he did have an opportunity to raise appropriate questions before it was initiated. Dr. Lazell stated that he believed "transport and release of coastal marsh alligators...especially to inland swamps, will be at best a cruel way to kill alligators...". That belief is totally erroneous and a careful review of previous relocation programs in the southeast as well as the Society's program very vividly demonstrates that not only do the alligators survive but reproduce as well. Before the Society released alligators in any locations, biologists examined the potential restocking areas to determine the quality of habitat involved. Records were kept on the location of the release, the number of alligators released, the sex and size of each, and they were individually tagged. From this recordkeeping, follow-up studies have shown that the survival rate has not only been high but reproduction has been observed in the re-stocked alligators as well. A number of areas have yet to demonstrate reproduction

success but this was expected since those alligators re-stocked were not yet sexually mature. If Dr. Lazell has any scientific information to dispute the Society's documents of our transplants, I hope he will share them with me.

While the Society is not opposed to the harvest of surplus alligators under carefully controlled conditions, we do not feel that marketing the hides of one species necessarily reduces the public's appetite for other similar species since most cannot tell the difference. Also, there seems to be an unfortunate trend in wearing apparel toward uniqueness. I agree with J.K. Bowler, Curator of Reptiles at the Philadelphia Zoological Garden that relocation of "alligators to suitable habitats within the natural range can hardly be equated to the introduction of exotic species."

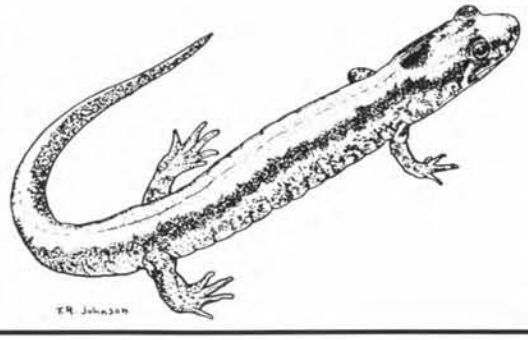
W. CARLYLE BLAKENEY, Jr., Southeast Regional Representative, National Audubon Society, P.O. Box 786, Charleston, S.C. 29402 ●

RESPONSE TO BOWLER'S LETTER ON ALLIGATORS

2 February 1977

Inasmuch as Bowler's letter of November 18, 1976 in Herpetological Review 7 (4) regarding alligators contains several common misimpressions, I feel a response is pertinent. I would like to address Bowler's information on alligators first, and general considerations on translocation effects second.

First, alligators and ecological barriers: This is a poorly understood subject. While there may be few truly genetically isolated alligator populations, on-going studies clearly document morphological and possibly biochemical differentiation between alligator populations from different geographic areas. These indicate some restrictions in gene flow and are of considerable biogeographic and other interest. Translocations could obfuscate the natural picture and interfere with future studies.



This, of course, might be a small price to pay for the recovery of the alligator over its natural range if, in fact, translocations were needed for attaining this goal. In actuality, alligators are not extirpated from any significant portions of their historic range with the possible exception of the Dismal Swamp area of southern Virginia and northeastern North Carolina (Joanen, 1974). Most, if not all, ecologically suitable areas for alligator translocation already have resident populations which could be expected to increase through natural processes and procedures if given adequate protection (even in Miami and New Orleans, where alligators do exist and occasionally cause problems).

In short, the alligator is not a beleaguered species clutching at the edge of extinction in desperate need of extensive human manipulation but, in fact, one with sizable populations over a considerable portion of its former range and in a phase of impressive and encouraging natural recovery given the protective legislation that now exists. The recent removal of some populations from the endangered species list and a reduction of others (the great majority of alligators) to a "threatened" rather than "endangered" status reflects this pattern of normal recovery.

As for translocation in general, I wish only to note that the "cruel death" of translocated animals is seldom the reason for opposing the practice. The possible introduction of new parasites and/or disease into the receiving population (geographic variation in parasites and disease within many species is well documented) and the possibility of obscuring natural patterns of variation and adaptation also need to be evaluated. From the practical view, of course, the need will usually be the deciding factor. If there is a need (which is not indicated for the alligator) there still must be careful consideration of the other factors before the best stocking population is selected. It would make poor biological sense to use Louisiana alligators to restock the Dismal Swamp or south Florida alligators to restock Oklahoma even if such undertakings were deemed desirable. I am not aware of any such considerations being given to any of the current alligator "restocking" programs with the possible exception of the Dismal Swamp State Park in North Carolina.

Although I heartily support Bowler's concern for an interest in the alligator, I feel his position on this issue is based on inadequate information of the current population levels and trends for the species and on a superficial review of the ecological implications of translocation programs.

CHARLES A. ROSS, Fish and Wildlife Service, U.S.D.I., Gainesville, Florida 32601. ●

BOWLER RESPONDS TO ROSS

8 February 1977

I am familiar with the taxonomy, ecology, and population dynamics of the American alligator, and I have personally observed the impressive recovery of this species in southeastern South Carolina. I did not mean to imply that we transport south Florida alligators to McCurtain County, Oklahoma. It may be acceptable to move surplus Louisiana alligators to Arkansas and Mississippi.

Perhaps I overreacted to Skip Lazell's letter, which was published in Herp Review 7 (3) but I feel that some biologists are unreasonably opposed to restocking and translocation programs of any kind. Such programs have saved some species of animals from extinction.

J. KEVIN BOWLER, Philadelphia Zoological Garden, 34th Street and Girard Avenue, Philadelphia, Pennsylvania 19104. ●

LEGISLATION AND RULEMAKING RE HERPS

Cooperation in conservation activities at all levels--Federal, state, local, and individual--is essential to effectively preserve endangered wildlife. It is important to keep our constituency informed of all rulemaking actions (e.g., notices of review, proposals, and final drafts), particularly those legislative activities involving reptiles and amphibians. The following information concerns "herps" affected by U.S. Federal legislation (as of 1 January 1977):

Final rulemaking (effective 7 February 1977): 50 CFR 17.

Alligator mississipiensis (American alligator)--Populations throughout Florida and in coastal areas of South Carolina, Georgia, Louisiana, and Texas have been reclassified from Endangered to Threatened status; populations inhabiting Alabama, Mississippi, North Carolina, Oklahoma, and inland portions of South Carolina, Georgia, Louisiana, and Texas are still classified as Endangered.

Final rulemaking (effective 22 February 1977): 50 CFR.

Sections 23.13 and 23.15 of the Endangered Species Convention (Federal Register Vol. 42, No. 35-Tuesday, February 22, 1977) dealing with prohibitions, permits, and exceptions relative to Endangered/Threatened international wildlife (i.e., herps).

Final rulemaking (effective 23 May 1977): 50 CFR 17.

a) Sections 17.1 and 17.2 implementing the Endangered Species Act of 1973 are amended to include wildlife designated in Appendices I, II, and III of the Endangered Species Convention (Federal Register Vol. 42, No. 35-Tuesday, February 22, 1977).

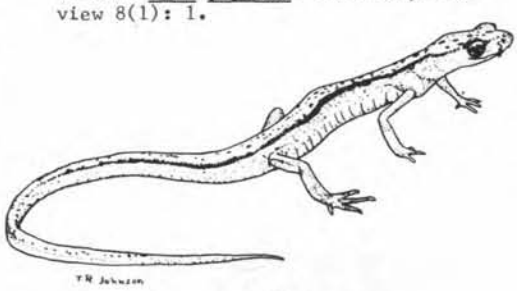
b) Section 23 added to 50 CFR involves rules covering Endangered/Threatened wildlife subject to the Endangered Species Convention (Federal Register Vol. 42, No. 35-Tuesday, February 22, 1977).

Proposed rulemaking: 50 CFR 16.

These proposed regulations will effect importation and interstate shipments of "injurious" wildlife; the proposal calls for listing a number of species of "herps" as "injurious" (e.g., several viperids, crotalids, elapids, rear-fanged colubrids, salamandrids, a pipid and bufonid)-see Federal Register, Vol. 42, No. 44-Monday, March 7, 1977.

In addition, Endangered status and critical habitat designation have been proposed for Ameiva polyps--the St. Croix ground lizard (10 January 1977) and Anolis roosevelti -- the giant anole (10 January 1977). Public comment closed on 8 April 1977 for these two forms.

THOMAS J. BERGER, Museum of Natural History, University of Kansas, Lawrence, Kansas 66045. ●



Geographic Distribution

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same. The standard format for a geographic distribution record is:

Scientific name (common name) as it appears in Conant (1956, 1975) or Stebbins (1966). Locality (use metric for distances). Date and collector(s). Identified or verified by. Place of deposition and catalogue number. Comments. Citation. Submitted by (give name and address).

Please submit new geographic distribution records in the standard format only to Joseph C. Mitchell, Graduate Program in Ecology, University of Tennessee, Knoxville, Tennessee 37916. Short manuscripts are acceptable when data cannot be adequately presented in the standard format.

Recommended citation for new geographic distribution records appearing in Herpetological Review is: Jones, J. 1977. Geographic distribution: Rana pipiens. SSAR Herp. Review 8(1): 1.

CAUDATA

AMBYSTOMA ANNULATUM (Ringed salamander). USA. ARKANSAS: Stone Co: Blanchard Springs Caverns Recreation Area, T15N, R11W, Sec. 6. 22 October 1976. D.A. Saugey. Verified by V. Rick McDaniel. Private collection of V.R. McDaniel, VRM 775-87, 810-13. First record for county and for Sylamore Ranger District, Ozark National Forest (Schuier, et al., 1972, Ark. Acad. Sci. Proc., XXVI: 61-66), and helps explain an earlier report from Sharp County (McDaniel. 1975, Herp. Rev. 6(4): 115). Further significance includes the fact that these 17 specimens were collected from a group of several hundred ringed salamanders apparently moving toward a small pond during a light rain on this night. A search of this area one week later revealed only one additional ringed salamander. Males examined had swollen cloacas, and females contained large numbers of apparently ripe eggs. The ringed salamanders were accompanied by smaller numbers of Plethodon glutinosus glutinosus, Plethodon dorsalis angusticlavius, Eurycea longicauda melanopleura, Eurycea lucifuga, and Ambystoma maculatum.

Submitted by: V. RICK MCDANIEL and DAVID A. SAUGEY, Division of Biological Science, Arkansas State University, State University, Arkansas 72467.

AMBYSTOMA GRACILE GRACILE (Northwestern salamander). USA. OREGON: Deschutes Co: 20.5 km SSW Sisters (T17S, R9E, Section 14), altitude 2000 m. Richard K. O'Hara. Oregon State University Museum of Natural History, OSU 10 724-6. Extends range eastward approximately 17 km and establishes a new county record (Snyder. 1963. Ambystoma gracile. Cat. Amer. Amph. Rept., 6). This is the first verified account of this species east of the Cascade Mountain crest.

Submitted by: RICHARD K. O'HARA, Department of Zoology, Oregon State University, Corvallis, Oregon 97331.

PLETHODON DUNNI (Dunn's Salamander). USA. WASHINGTON: Lewis Co: 6.9 km N Pe Ell. 21 March 1977. Hugh G. Hanlin. OSU Museum of Natural History, OSU 10777 - 10782 (6 specimens). First record for county and extension of range 13.8 km NE of previous northern limit. Brodie, 1970, Herpetologica 26[4]).

Submitted by: HUGH G. HANLIN, Department of Zoology, Oregon State University, Corvallis, Oregon 97331.

PLETHODON YONAHLOSSEE (Yonahlossee salamander). USA. VIRGINIA: Pulaski Co: 18 km SE Pulaski. 3 October 1976. D.W. Ogle. Verified by Richard L. Hoffman. USNM 232723. Northern extension of range and first record for county. (Highton. 1971. pp. 139-188, in P.C. Holt, ed., The distributional biota of The Southern Appalachians. Part III. Vertebrates. Res. Div. Monog. 4, V.P.I. and St. Univ., Blacksburg, Va.).

Submitted by: D.W. OGLE, Biology Department, Virginia Highlands Community College, Abingdon, Virginia 24210.

SALIENTIA

OSTEOPILUS SEPTENTRIONALIS (Cuban Treefrog). USA. FLORIDA: Indian River Co: E, SW, Central Vero Beach, 6 specimens. 8 July, 13 September, 15 September 1976. S. Myers and M. McGranahan. Florida State Museum, FSM 37686-37691. 13 August 1975. J.D. Edman and H.W. Kale, Florida Med. Entom. Lab collection, uncataloged. St. Lucie Co: Port St. Lucie. Summer 1974. G. Evans and H.W. Kale, specimen released. St. Lucie Power Plant, Hutchinson Is., S. Hill, observed only. These localities lie 141.4 km N of Broward-Palm Beach County line, the northern most known locality (Lee, 1969, Florida Natur., 42[3]: 117-120). These records suggest the population is moving northward.

Submitted by: STEVEN MYERS, Department of Biology, Florida Technological University, Orlando, Florida 32816.

RANA AREOLATA CIRCULOSA (Northern Crawfish Frog). USA. ARKANSAS: White Co: 0.7 km N Searcy, Ark. Rt. 16. 8 March 1977. M.V. Plummer. Harding College Dept. Biol., HCDB 1196-99. Extends range ca 115 km SW of nearest locality in Craighead County (Byrd and Hanebrink, 1974, Herp. Review 5[3]: 69).

Submitted by: MICHAEL V. PLUMMER, Department of Biology, Harding College, Searcy, Arkansas 72143.

SCAPHIOPUS HOLBROOKI HURTERI (Hurter's Spadefoot). USA. ARKANSAS: White Co: Searcy (T8N R7W S36). 27 March 1977. M.V. Plummer. Harding College Dept. Biol., HCDB 1239-65. Extends range ca 100 km SE of nearest locality in Stone County (Schuier, et al., 1972, Proceed. Ark. Acad. Sci. 26: 61-66).

Submitted by: MICHAEL V. PLUMMER, Department of Biology, Harding College, Searcy, Arkansas 72143.

SAURIA

ANOLIS PORCATUS (Cuban Green Anole). DOMINICAN REPUBLIC. DISTRITO NACIONAL: 5.4 km N on Carretera Duarte from jct. with Avenida Abraham Lincoln in Santo Domingo. 2 October 1976. Native collectors for Patricia G. Haneline. Museum of Comparative Zoology, Harvard University, MCZ 151539. Extends the range of this Cuban species, introduced into the Dominican Republic, approximately 8 km from "La Feria" in downtown Santo Domingo, where it was formerly believed to be confined to an area only several blocks in size (Schwartz and Thomas, 1975. Carnegie Mus. Nat. Hist. Spec. Publ. 1, p. 97).

Submitted by: PATRICIA G. HANELINE, Museum of Comparative Zoology, Harvard University, Cambridge, Massachusetts 02138.

ANOLIS SAGREI (Brown Anole). USA. FLORIDA: St. Johns Co: Saint Augustine (Old St. Augustine). W end Aviles Street. 21 September 1975. R.R. Doyle. Florida State Museum, UF 34404. Extends the known range of this introduced species 240 km NE from Tampa-St. Petersburg area (Conant, 1975, A Field Guide to Reptiles and Amphibians).

Submitted by: PETER MEYLAN, Florida State Museum. Gainesville, Florida 32611.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA. FLORIDA: Duval Co: Jacksonville, Myrtle Avenue at Florida Gas Co. Building. April or May 1970. B.U. Mansell. Florida State Museum, UF 37275 (formerly BUM 871). This record extends the known range of this introduced species 112 km NE from Gainesville where it has been established since 1956 (King, 1959, Jour. Fla. Acad. Sci.).

Submitted by: PETER MEYLAN, Florida State Museum, Gainesville, Florida 32611.

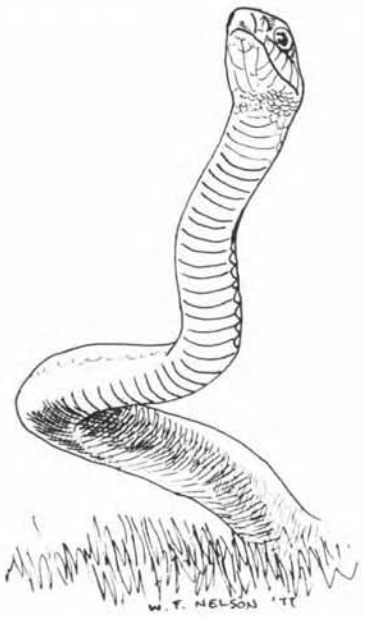
OPHISAURUS COMPRESSUS (Island Glass Lizard). USA. FLORIDA: Wakulla Co: Shell Point. 10 August 1976. P. Moler. Florida State Museum, UF 37276. This record, along with those reported by Godley (1976, Herp. Rev. 7[3]: 122-123), indicate continuity in the range of O. compressus along the Gulf coast of Florida from St. George Island to Peninsular Florida.

Submitted by: PETER MEYLAN, Florida State Museum, Gainesville, Florida 32611.

SERPENTES

REGINA GRAHAMI (Graham's Crayfish Snake). USA. ILLINOIS: Carroll Co: Savanna, Mississippi Palasades State Park. 23 August 1970. David S. Greenfield and Harlan D. Walley. HDW collection #1095. First record from county and extends range about 96.5 km N of nearest previous record from Rock Island County (Smith, 1961, Illinois Nat. Hist. Surv. Bull. 28 [1]: 1-298). Most northern record for the species.

Submitted by: HARLAN D. WALLEY, Department of Biology, Northern Illinois University, DeKalb, Illinois 60115. ●



THE HERPETOFAUNA OF OSSABAW ISLAND, CHATHAM COUNTY, GEORGIA

Six species of amphibians and sixteen species of reptiles were collected or observed on Ossabaw Island from March 27 through April 2, 1975. Ossabaw Island is privately owned and its herpetofauna has not been previously described. Martof (1963, Herpetologica 19: 70-72) described the herpetofauna of nearby Sapelo Island and Anderson (1976. Herp. Rev., 7[4]: 179-180), the herpetofauna of Jekyll Island. Ossabaw Island is separated from the mainland by an extensive salt marsh. Specimens collected were deposited in the American Museum of Natural History.

AMPHIBIANS: Eurycea quadridigitata (AMNH 95796-98) was abundant throughout the island under moist decaying logs; Plethodon glutinosus glutinosus (AMNH 95799 - 800) was found under decaying logs on the south end of the island; Bufo terrestris (AMNH 95801-03) was abundant throughout drier areas of the island and is often found in hollows at the bases of standing trees; Gastrophryne carolinensis (AMNH 95814) was found after a midday rain under a board on the south end of the island; Hyla squirella (AMNH 95804-05) was abundant in trees and moist leaf litter and large choruses were heard at night; Limnaoedus ocularis (AMNH 95806-13) was found in moist situations throughout the island. Very abundant, large choruses were heard at night.

REPTILES: Alligator mississipiensis. Three individuals were observed at midday in Gator Pond. All had total lengths under two meters; Anolis carolinensis carolinensis (AMNH 14581 - 82) was abundant throughout the island: Cnemidophorus sexlineatus sexlineatus (AMNH 114590) was found DOR on a road along the southeast section of the island; Eumeces inexpectatus (AMNH 114588-89) was very abundant and was usually found under woodpiles around edges of marshes; Scincella lateralis (AMNH 114582-87) was extremely abundant, especially in moist leaf litter; Ophisaurus ventralis (AMNH 114580) was found on south end of the island in forest; Cemophora coccinea copei AMNH 114591) was found under a board in sand, adjacent to a beach; Coluber constrictor priapus (AMNH 114592-93) was found abundantly in moist woodlands, dry, sandy areas, and woodpiles; Crotalus adamanteus (according to Mrs. Clifford B. West, the owner of Ossabaw) is occasionally seen on the island. Mrs. West showed me two large skins of eastern diamondback rattlesnakes which had been shot on the island; Lampropeltis getulus getulus (AMNH 114594-95 was the most abundant serpent encountered, most often found in moist situations near water; Opheodrys aestivus (AMNH 114596) was found on the west border of Goose Pond; Thamnophis sauritus sackeni (AMNH 114597-98) was found around the edge of small, temporary freshwater pool. Both were active when observed and may have been foraging for Limnaoedus ocularis which was abundant around the perimeter of the pool; Thamnophis sirtalis sirtalis (AMNH 114599-600) was very abundant, especially in brush piles. One was palped and contained two large Bufo terrestris; Caretta caretta caretta nestings on the beaches of Ossabaw are being studied by the University of Florida and the University of Georgia Institute of Natural Resources; Dermochelys coriacea coriacea. Mrs. West showed me a large leatherback skull taken from a turtle found dead on an Ossabaw beach; Chrysemys scripta scripta (AMNH 114601) shells were found in vegetation around Gator Pond.

Submitted by: STEVEN B. RINGLER, Bard College, Annandale-on-Hudson, New York 12504. ●

DISTRIBUTIONAL RECORDS OF AMPHIBIANS AND REPTILES FROM PUERTO RICO

We have taken Anolis occultus in two areas in the northern limestone periphery of PUERTO RICO: 10 km airline W. Manati, 50 m (RT 3759-62) and 2 km S Pueblito de Ponce, Montanas Aymamon, ca. 200 m (RT 3879-84). The present records markedly extend the known geographic, elevational, and ecological ranges of the species, heretofore known only from upland forests above 600 m. Although the natural vegetation of the northern coastal plain is termed the "moist limestone forest" (Little and Wadsworth, 1964, U.S. Dept. Agric. Handbook No. 249), drainage factors on the mogotes result in vegetation with a xerophytic character, including for example the trees Bursera simaruba and Bucida buceras. Also at the locality 10 km airline W Manati we obtained Sphaerodactylus klauberi (RT 3695) and Diploglossus pleei (RT 3698-3708), both extreme peripheral and low elevation records for otherwise interior, upland species.

On the xeric southern coastal periphery, we obtained Bufo lemur (RT 4075) 6 km airline NNW Santa Isabel (xeric pasture-woods), and Mabuya mabouya (RT 4215) about 2 km by road NE Descalabrado (xeric woods and second-growth scrub at edge of cultivation). Both of these species are known on Puerto Rico from relatively few records. Ameiva wetmorei (RT 4170) taken in the scrubby hills just north of Punta Cuchara (ca. 4 km airline SW Ponce) constitutes an eastward range extension on the mainland of Puerto Rico.

Submitted by: RICHARD THOMAS and KIM R. THOMAS, Department of Biology, University of Puerto Rico, Rio Piedras, Puerto Rico 00931. ●

NEW DISTRIBUTIONAL RECORDS FOR AMPHIBIANS AND REPTILES FROM THE PROVINCES OF CATAMARCA, LA RIOJA, AND CORDOBA, ARGENTINA

During the course of field work for the Desert Scrub Subprogram of the International Biological Program, numerous reptiles and amphibians were collected from the provinces of Catamarca, La Rioja, and Cordoba. The species listed here represent significant range extensions and, with the exception of Pleurodema nebulosa and Homonota horrida all represent the first recorded occurrence of the species in the province. Catalogue numbers refer either to the Texas Natural History Collection (TNHC) or the Carnegie Museum (CM).

PLEURODEMA NEBULOSA. LA RIOJA: Mazan (TNHC 45105-108) and Rio Salada 15 km S of Mazan (TNHC 44919); CATAMARCA: Rt. 62, 5 km W of Andalgala (TNHC 44950-965) and Rt. 1, from 4 to 35 km S of Andalgala (TNHC 45115-125, 45126-45135, and 45077-45113). The preceeding specimens represent a range extension of approximately 70 to 110 km eastward from that previously reported by Barrio (Physis, 1964, 24: 471-489). HOMONOTA UNDERWOODI. LA RIOJA: Rt. 38, 15 km W of Chamical (TNHC 46801); CATAMARCA: Rt. 62, 6 km W of Andalgala (TNHC 44941) and Rt. 1, 4 to 33 km S of Andalgala (TNHC 46865, 46720, 46867, 46694, and 44932). The Andalgala records represent a range extension of approximately 390 km to the northeast from that reported by Kluge (1965, Bull. S. Calif. Acad. Sci. 64: 127-131). HOMONOTA HORRIDA. CATAMARCA: Andalgala: (TNHC 45104), Rt. 62, 6 km W of Andalgala (TNHC 44938), Rt. 1, 17 km S of Andalgala (TNHC 46734-435) and Poman (TNHC 46709-712, 46900, 46692, and 44932). These are the first specimens reported from the departments of Andalgala and Poman. GYMNOPHTHALMUS RUBRICAUDUS. CATAMARCA: Rt. 60 approximately 15 km S of the Junction of Rt. 1, in the Sierra de Ambato (CM 63617). This is the first specimen reported from Catamarca. LEPTOTYPHLOPS UNGUIROSTRIS. CORDOBA: Rt. 60, 5 km S of Totoralejas (TNHC 46675), CATAMARCA: Rt. 62, 6 km W of Andalgala (CM 61537), Rt. 1, 12 km S of Andalgala (TNHC 46679, 46688, and CM 61538) and Rt. 1, 14 km S of Andalgala (CM 61539). These are the first specimens actually reported from Catamarca and Cordoba. The species has previously been reported from San Juan and Santiago del Estero (Peters and Orejas-Miranda, 1970, U.S.N.M. Bull. No. 297: 1-347). LEPTOTYPHLOPS BORRICHIANUS. LA RIOJA: Chamical: (TNHC 46702). This is the first record for the province of La Rioja and represents a range extension of approximately 320 km northeast from the vicinity of Mendoza (Peters and Orejas-Miranda, 1970, U.S.N.M. Bull. No. 297: 1-347). LEPTOTYPHLOPS MELANOTERMUS. CORDOBA: Cordoba (TNHC 46701), CATAMARCA: Rio Poman 4 km E of the town of Poman (TNHC 44821). This species has been previously recorded from northern Argentina as far south as Santa Fe (Peters and Orejas-Miranda, 1970, J.S.N.M. Bull. No. 297: 1-347). THAMNODYNASTES SP. CATAMARCA: Cuesta de Minas Capillitas (CM 61549), Minas Capillitas (TNHC 44843), La Banderia. Albalos, Baez, and Nader (1964, Acta Zool. Lillo. 20: 211-283) reported on one specimen of Thamnodynastes strigilis from Santiago del Estero, but the genus has not been reported from Catamarca. PHIMOPHIS VITTATUS. LA RIOJA: Rt. 38, 4 km E of Chamical (TNHC 46904); Rt. 38, 12 km W of Chamical (TNHC 46878), CATAMARCA: Andalgala (TNHC 44940, 61544), Rt. 1, 14 km S of Andalgala (TNHC 44834), Rt. 1, 20 km S of Andalgala (TNHC 46915), Rio Canada (TNHC 44858), Poman (CM 61546) and junction of Rt. 1 and Rt. 60 (TNHC 46864). Peters and Orejas-Miranda (1970, U.S.N.M. Bull No. 297: 1-347) reported this species from Entre Rios and Santiago del Estero northward in Argentina. The Chamical specimens represent a range extension of approximately 280 km to the WSW.

DISTRIBUTIONAL NOTES ON KIRTLAND'S WATER SNAKE, CLONOPHIS KIRTLANDI (KENNICOTT)

This note reports new locality records which extend the range of this species in ILLINOIS, INDIANA, KENTUCKY, and OHIO. Abbreviations are: KU, Museum of Natural History, University of Kansas, Lawrence; RSF, personal collection of R.S. Funk; UCM, University of Colorado Museum, Boulder; and UMMZ, University of Michigan Museum of Zoology, Ann Arbor.

ILLINOIS: Coles Co: Lake Paradise spillway, 9 km SW Mattoon. 16 July 1976. R.S. Funk. Verified by J.K. Tucker. RSF 3665. Extends the range 24 km SW from nearest record in Charleston, Coles County (Smith, 1961, Ill. Nat. Hist. Surv. Bull. 28[1]: 78-79).

INDIANA: Orange Co: Valeen. April 1972. D. Cassady. UMMZ 131130. Extends the range 53 km SW from nearest Indiana record (Muskatatuk lowlands near Little York) in Washington County (Minton, 1976, Indiana Acad. Sci. Monogr. 3: 1-346) and 53 km NNW from populations in New Albany, Floyd County, Indiana (Conant,

1943, Am. Midl. Nat. 29[2]: 313-341).

KENTUCKY: Campbell Co: May 1959. G.T. McDuffie. KU 144717. Kenton Co: Ludlow. October 1960. D.E. Haggard. KU 144716. The only previous Kentucky records documented by specimens are in Jefferson and Ohio counties over 145 km SW (Conant, 1943, Am. Midl. Nat. 29[2]: 313-341). These records extend the range south of the Ohio River; nearest previously reported populations are in Cincinnati, Hamilton County, Ohio, north of the Ohio River.

OHIO: Cuyahoga Co: Cleveland. May 1945. KU 82695. Extends the range 80 km NE from New London, Huron County (Conant, 1943, Am. Midl. Nat. 29[2]: 313-341). Wayne Co: 5.2 km N. Rittman. 28 April 1960. J. Dolan. UCM 35866. Extends the range 56 km E from New London, Huron County (Conant, 1943. Am. Midl. Nat. 29[2]: 313-341) and 59 km S of Cleveland record reported above. These new Ohio records are the nearest to the probably disjunct populations 150 k m SE in Pennsylvania.

Acknowledgements: We thank S. Wu (UCM) and A.G. Kluge (UMMZ) for making specimens available for examination.

Submitted by: JOHN K. TUCKER and RICHARD S. FUNK, Department of Biological Sciences, Illinois State University, Normal, Illinois 61761; and JOSEPH T. COLLINS, Museum of Natural History, University of Kansas, Lawrence, Kansas 66045. ●

News Notes

HOBART SMITH RECOGNIZED

The University of Colorado has awarded its fifty-second Lectureship on Research and Creative work to Hobart M. Smith. Hobart Muir Smith is one of the leading herpetologists in the world, noted primarily for his massive and distinguished contributions to the classification and evolutionary biology of reptiles and amphibians. An internationally recognized specialist on the herpetofauna of Mexico, he has also made important contributions to the fields of comparative anatomy, paleontology, biological bibliography and biography, ecology, and animal behavior.

This breadth of knowledge is manifested in Dr. Smith's publication record of approximately 30 books and 700 articles. One of his major achievements is The Herpetology of Mexico, a now classic document which is being revised and expanded. Another large-scale project is the preparation of an index to the world scientific literature on Mexican herpetology. To date, this has resulted in four published volumes, one almost completed volume, and four in the planning stage. The first two published volumes alone contain a list of approximately 9,000 references, and the last two about 98,000 citations derived from those references plus about 1,500 supplementary ones. His textbook of comparative anatomy is a unique contribution. First published nearly 30 years ago, it remains a standard reference book.

As teacher, Dr. Smith is able to direct students to research projects which promise to lead to new and significant findings. This advice is extremely useful in the training of undergraduate and graduate students and in the development of young faculty as well as in the systematic advancement of science.

Hobart Smith received graduate degrees from the University of Kansas and joined the University of Colorado faculty in 1968, serving as chairman of the Department of Environmental, Population, and Organismic Biology from 1970 to 1974. Hobart Smith is a scholar's scholar, a gentleman and a gentle man. The Lectureship not only honors him but brings credit to the award.

ANDERSON MEMORIAL ESTABLISHED

The tragic and untimely death of Jim Anderson has left us all with a sense of great personal and professional loss. His former colleagues in the Department of Zoology and Physiology at Rutgers are now establishing a James D. Anderson Memorial Lecture Series in his honor whereby eminent ecologists will be invited to speak on campus on a regular basis. This form of tribute is particularly appropriate in view of Dr. Anderson's commitment to teaching and research in ecology. Contributions for a fund to support this endeavor are needed.

Checks should be made out to The Rutgers University Foundation and forwarded to:

The Rutgers University Foundation
191 College Avenue
New Brunswick, New Jersey 08903

This appeal is outside of the normal Annual Fund appeal of the Foundation. Your contribution is tax deductible, of course.

FUTURE SSAR MEETINGS

1978--SSAR 21st Annual Meeting in May-June at Arizona State University, Tempe. M. J. Fouquette, SSAR Local Meeting Chairman.

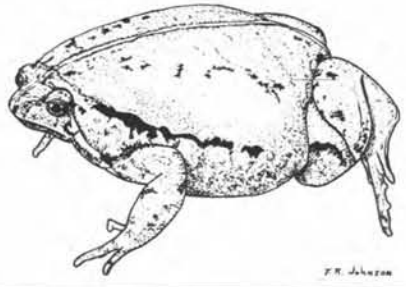
1979--SSAR 22nd Annual Meeting in August at the University of Tennessee, Knoxville.

SSAR FACSIMILE COMMITTEE

The Society for the Study of Amphibians and Reptiles is pleased to announce the 1977 Editorial Committee and staff for its series Facsimile Reprints in Herpetology.

Kraig Adler, Editor, Langmuir Laboratory, Cornell University, Ithaca, New York 14853 (USA).

Jaime Villa, Assistant Editor, Apartado, Postal 427, Managua (Nicaragua).



Editorial Committee: Eddie M. Ashmore, Louisville, Kentucky (USA); Jan Caldwell, Biological Survey of Kansas (USA); Harold G. Cogger, The Australian Museum (Australia); Federico Medem M., Estacion de Biologia Tropical (Colombia); Gunther Peters, Museum fur Naturkunde der Humboldt-Universitat (Germany); Rolande Roux-Esteve, Museum National d'Histoire Naturelle (France); and Jay M. Savage, University of Southern California (USA).

HERP STAMP BOOK AVAILABLE

Lower Vertebrates: Fishes, Amphibia and Reptiles on Stamps of the World is a handbook prepared by George A. Bearse, Willard F. Stanley, Maynard S. Raasch, Ursula Stahl, E.O. Bookwalter, Robert E. Gordon and Malvin L. Skaroff, and contains a taxonomic listing and a country listing in conformity with the style of previous biological stamp handbooks on Birds and Mammals.

The checklist of amphibians and reptiles presents issues from 114 stamp producing entities. Among the lists are to be found 29 stamps depicting 23 species of Frogs and Toads, five species of Salamanders on 11 stamps, 20 species of Turtles on 109 stamps, 51 species of Lizards on 84 stamps, 57 species of Snakes on 126 stamps, 12 species of Crocodiles on 127 stamps plus 38 fossil species on 61 stamps.

The volume is 120 pages including hundreds of stamp illustrations on 8 full-page plates and an artistic cover. Regularly priced at $8, introductory orders are now being accepted at a special price of only $7 from the American Topical Association, 3308 North 50th Street, Milwaukee, Wisconsin 53216.

DAS TIERREICH ISSUE AVAILABLE

Duellman, William E. 1977. Liste Der Rezenten Amphibien und Reptilien: Hylidae, Centrolenidae, Pseudidae. Das Tierreich, Lief. 95, pp. i-xix, pp. 1-225. Walter de Gruyter & Co., D-1000 Berlin 30, Genthiner Strasse 13, Germany. 280 DM (=$115.70).

This checklist of the 40 genera and 603 species of hylid, centrolenid, and pseudid frogs covers the literature through 1974. Included in the accounts of each species and subspecies are type localities, location and catalogue numbers of type specimens, all nomenclatural combinations, authorities for all synonymies and for current usage, statements of geographic distribution, and references to pertinent literature. The volume is completely indexed for all generic and trivial names.

SECOND ANNUAL REPTILE SYMPOSIUM

Announcing the 2nd Annual Reptile Symposium on Captive Propagation and Husbandry sponsored by Baltimore Zoological Society, Catoctin Mountain Zoological Park, Zoological Society of Philadelphia, and Reptiland. This year's Symposium is hosted by Northern Ohio Association of Herpetologists, Cleveland Museum of Natural History, and Case Western Reserve University. It is to be held in Cleveland, Ohio on the grounds of Case Western Reserve University and Cleveland Museum of Natural History on Thursday, Friday, and Saturday of June 23, 24, and 25.

Preregistration can be obtained by writing to: Bob Johnson, Attn: Reptile Symposium, c/o Baltimore Zoo, Druid Hill Park, Baltimore, Maryland 21217.

MEXICAN FAUNA CONFISCATED

The United States Fish and Wildlife Service has recently confiscated a variety of Mexican fauna at the port of entry in El Paso, Texas.

Among those specimens confiscated were the following: 30 Mexican tarantulas; 11 Mexican boa constrictors; 2 Long-nosed snakes; and 1 Mexican lyre snake.

Arrangements can be made through the El Paso Zoological Park for relocating any or all of the above specimens in zoological facilities in the United States. All transactions are to be considered temporary; but it is hoped that the cooperating institutions will be made permanent recipients of individual specimens at a later date, pending the result of the litigation. For more information contact: Raymond Arras, Director, El Paso Zoological Park, Evergreen & Paisano, El Paso, TX 79905.

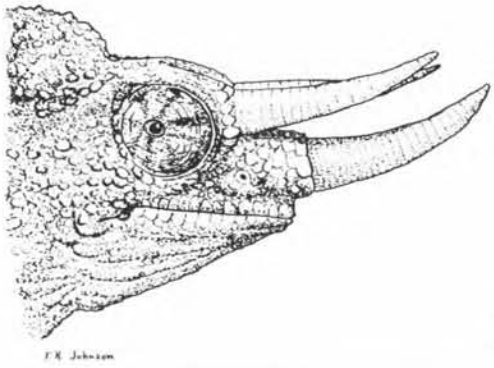
ERRATA FOR HR 7(2)

Page 84. Ontogenetic shifts in food habits of a crayfish eating specialist. Regina alleni (Serpentes: Colubridae). Line 3, "(200 mm TL)" should read "(< 200 mm TL)"; lines 6-7, "Adult prey items identified in juvenile R. alleni feed primarily on hard-shelled procambarid crayfish." should read "Adult R. alleni feed primarily on hardshelled procambarid crayfish."

ERRATA FOR HR 7(3)

Distances in the following Geographic Distribution reports should be converted to correct kilometer values by multiplying the published distances by 0.617:

French, T. W. Gyrinophilus porphyriticus, p. 122.
Garton, J.S. and B.L. Sill. Seminatrix pygaea, p. 123.
Godley, J.S. Ophisaurus compressus, p. 122.
McCoy, C.J. Storeria dekayi texana, p. 123; Thamnophis radix haydeni, p. 124; Tropidoclonion lineatum, p. 124.
Means, B. Heterodon nasicus gloydi, p. 123.
Stephan, D.L. and A.C. Braswell. Manculus quadridigitatus, p. 125--44 km distance is correct as published.



ERRATA FOR HR 8(1)

Page 1, Table of Contents: "In Memorium" should read "In Memoriam."

Page 5, col. 1, para. 2, last line "369)." should read "1960: 369)."

Page 5, col. 2, para. 3, lines 5-6 + photo caption: "Miniola" should read "Mineola."

Regional Society News

ST. LOUIS HERPETOLOGICAL SOCIETY

In the past, the SLHS has undertaken a number of special projects to promote the conservation of amphibians and reptiles, educate the novice herpetologist in the proper care and housing of amphibians and reptiles in captivity, and has promoted the union of professional and amateur herpetologists for the betterment of the field.

Presently, the St. Louis Herpetological Society has published a "snake" poster to help educate the public to the fact that so many of our harmless snakes are needlessly killed. It is the hope of the organization that the poster will show that snakes are an interesting and beneficial part of our outdoors. These attractive posters measure 11 x 16 inches, are printed on heavy white, yellow, or green paper, and can be ordered for 50¢ each from:

The St. Louis Herpetological Society
P. O. Box 9216
St. Louis, Missouri 63117

The SLHS is working with the local Natural History Museum to establish educational museum displays on a wide range of herpetological subjects. The theme for the first joint-effort display will be: "The Salamanders of the Missouri Ozarks." Sometime this summer, the SLHS will hold another auction to raise funds for future projects. Books, herpart, aquariums, cages, snake hooks, photographs, animal food, etc. are some of the items to be auctioned.

Please send news information on YOUR regional herpetological society to the section editor (see inside front cover for address). Include new projects, special educational programs, fund raising efforts, etc.

A few extra copies of the patrons' set of Holbrook color plates are being offered for sale. All proceeds will be assigned to the SSAR Conservation Fund, which is used to further the Society's activities in the conservation of amphibians and reptiles.

Plates measure 10 by 13 inches and are printed on heavy paper stock suitable for framing. Supplies of many plates are quite limited; orders will therefore be filled on a first-come, first-served basis. Prices reflect availability.

JOHN EDWARDS HOLBROOK, watercolor portrait by David M. Dennis (1976), artist's proof signed by Mr. Dennis but unnumbered	$25.00
EASTERN BOX TURTLE, Terrapene carolina	8.00
DIAMONDBACK TERRAPIN, Malaclemys terrapin	10.00
RIVER COOTER, Chrysemys c. concinna	10.00
SLIDER, Chrysemys c. hieroglyphica	10.00
HAWKSBILL TURTLE, Eretmochelys imbricata	10.00
FENCE LIZARD, Sceloporus undulatus	10.00
COLLARED LIZARD, Crotaphytus collaris	10.00
COAST HORNED LIZARD, Phrynosoma coronatum	10.00
FIVE-LINED SKINK, Eumeces fasciatus	8.00
CANEBRAKE RATTLESNAKE, Crotalus horridus atricaudatus	8.00
EASTERN CORAL SNAKE, Micrurus fulvius	8.00
RAINBOW SNAKE, Farancia erytrogramma	8.00
BANDED WATER SNAKE, Natrix fasciatus	10.00
EASTERN HOGNOSE SNAKE, Heterodon platyrhinos	10.00
PICKEREL FROG, Rana palustris	10.00
GRAY TREEFROG, Hyla versicolor	10.00
GREAT PLAINS TOAD, Bufo cognatus	10.00
BLACK-BELLIED SALAMANDER, Desmognathus quadramaculatus	10.00
MUDPUPPY, Necturus maculosus	8.00

All shipments will be sent postpaid. Send order with payment to Dr. Henri C. Seibert, Morton Hall, Ohio University, Athens, Ohio 45701, U.S.A. Make checks payable to "SSAR"; receipts sent on request only.

Snakes: A Natural History

Second Edition

By H.W. PARKER, revised and enlarged by A. G. C. GRANDISON

Skull of the Malaysian pipe snake.

Enhanced by 16 full-color plates showing 32 species from all over the world, this fascinating guide offers an authoritative account of the history of snakes and their habits and characteristics—from the primitive, harmless, burrowing snakes to the venomous vipers and cobras.

After tracing the history of snakes from their earliest ancestors, the authors discuss the differences and resemblances between snakes and lizards. They then deal with the environments of snakes, their senses, their diet, and the capture of their prey. Also discussed are their enemies and ways of defending themselves, courtship patterns, reproduction, growth, and development. *Published with the British Museum (Natural History).*

16 color plates, 18 diagrams, 10 drawings.
Cloth $8.95; Paper $3.95

NEW BOOK ANNOUNCEMENT

AMPHIBIANS OF MISSOURI

by Tom R. Johnson

Fifth in a series of illustrated, readable guides to the vertebrate animals of Kansas and neighboring states. This book contains accounts of the 41 kinds of amphibians in Missouri with descriptions of habitats and habits keys, food preferences, reproductive modes, plus maps, photographs and illustrations by the author. Also included is a comprehensive list of other publications on Missouri amphibians.

Retail price (publication date: August 1977) . . . . . $5.00.

All sales are final. Payment must accompany order. Kansas residents add 3.5% sales tax. FOR ALL ORDERS, add 50¢ for handling.

Payment enclosed $_____.

CONSERVATION ADDENDUM

The U. S. Fish and Wildlife Service, Office of Endangered Species, Washington, D. C. 20240, is considering that the Pine Barrens treefrog (Hyla andersoni) be listed as an Endangered Species, and that the golden coqui (Eleutherodactylus jasperi) be listed as Threatened. Persons desiring to comment on these two proposals should write to the Director USFWS BEFORE 5 July 1977. Refer to bulletin FWS/OES/P35/(Eleutherodactylus) or . . . /P36/(Hyla). Information on locations of critical habitat are especially solicited.

An adult Phyllobates lugubris. Photographed by Harry Husberg.

An adult western bird-voiced treefrog (Hyla avivoca) from the Pine Hills of Union County, Illinois. Collected by Tom R. Johnson and Ronald A. Brandon on 8 June 1976. Photograph by Tom R. Johnson and Ronald A. Brandon.

A caiman in the Reptile House of the St. Louis Zoo. Photograph by Tom R. Johnson.

An adult Bufo americanus copei from Moosonee (James Bay) in Ontario, Canada. Photographed by Robert Hodge, University Museum, University of Alaska, College, Alaska 99701.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of Herpetological Review in 1967 (Corson Hirschfeld, Editor):

> "Herpetological Review incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the Review will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Now in its tenth year, Herpetological Review remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the Journal of Herpetology -- see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Authors are urged to write the editors before submitting feature-length articles. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles are desired. Submissions should be black-and-white, 8 X 10, glossy prints, and should be accompanied by a descriptive caption and exposure data. The name and address of the contributor should be taped or penciled on the back of each print. Please DO NOT send photographs before corresponding with the editors about them. Return of unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions can be supplied if desired. Contributors will receive ordering information prior to publication of their material. Herpetological Review will accept commercial advertising. Rates and copy information are available from the editors.

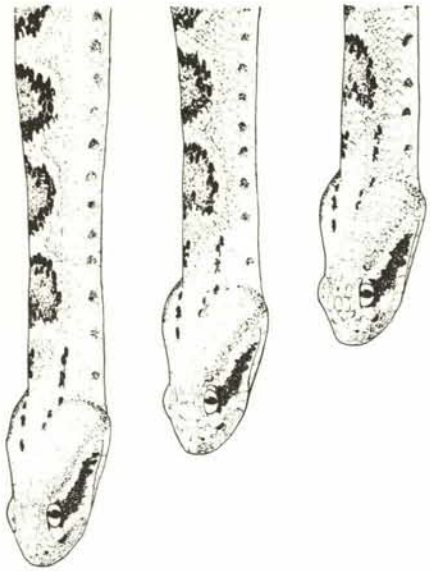
SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the Journal of Herpetology (four issues per year), Herpetological Review (four issues per year), Herpetological Circulars, and several Facsimile Reprints in Herpetology. Members may purchase other Society publications at reduced rates.



Annual Dues

Student Member	$ 8.00
Regular Member	10.00
Sustaining Member	15.00
Contributing Member	20.00
Institutional Subscription	20.00

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of the SSAR. For information regarding SSAR membership, write to:

Henri C. Seibert
SSAR Treasurer

ANNOUNCEMENT
JOINT ANNUAL MEETING

HERPETOLOGISTS' LEAGUE

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

sponsored by
THE UNIVERSITY OF KANSAS
with the cooperation of
THE KANSAS HERPETOLOGICAL SOCIETY
in
LAWRENCE, KANSAS U.S.A.
7-13 AUGUST 1977

FEATURED SYMPOSIUM:

The South American Herpetofauna: Its Origin, Evolution and Dispersal

THE PROGRAM:

Sunday, 7 August.—	SSAR Board Meeting
Monday, 8 August.—	Registration — Herpetologists' League Executive Council Meeting — Regional Society Meetings
Tuesday, 9 August.—	Contributed Papers — Social (evening)
Wednesday, 10 August.—	Contributed Papers — Picnic (evening)
Thursday - Saturday, 11-13 August.—	Symposium: The South American Herpetofauna

GENERAL INFORMATION:

Pre-registration Forms, including the **Call for Papers** and general information about the meetings will be mailed to society members in March.

The **deadline** for **abstracts** is **Monday, May 2, 1977.**

The **deadline** for **pre-registration** is **Friday, July 15, 1977.**

Pre-registration Fee of **$12** is due no later than July 15, 1977.

Registration Fee on or after 8 August will be **$17.**

Dormitory Housing is available at the following rates:
$7.50 per day per person: double occupancy — $10.00 per day per person: single occupancy

Camping Facilities for tents and recreational vehicles are available at the Lawrence KOA.

Child Care Facilities and Activities will be arranged if there is sufficient need and interest.

Transportation: Individuals planning to travel by air should make reservations into Kansas City International Airport (KCI) and book space on Lawrence Aviation commuter flights between KCI and Lawrence. Transportation between the Lawrence airport and the city of Lawrence will be provided if the Local Committee is notified in advance of times of arrival and departure.

LOCAL COMMITTEE CHAIRMAN:

William E. Duellman
Museum of Natural History
The University of Kansas
Lawrence, Kansas 66045
(913) 864-3342

Annual Meeting News

SSAR 1976 ANNUAL MEETING (OXFORD, OHIO)

Jim Vial called the business meeting to order and noted that, in the absence of a quorum, the meeting must be considered informative rather than official. Vial proceeded to introduce the members of the Board and notified the membership that a by-law amendment had been approved last year that now provided for a total of six directors instead of the four previously. Vial read the list of candidates for the respective offices as follows--Chairman Elect: Joseph T. Collins, Gary Ferguson; Secretary: Stephen R. Edwards; Treasurer: Henri Seibert; Directors-at-Large, Directors 1 and 2 (1977-1980; representing regional societies, wildlife management and zoos): Stanley Dyrkacz, Michael C. Long, Tom Johnson, and James B. Murphy; Director 3 (1977; general SSAR membership): Roy McDiarmid, Norm Scott. Vial asked for additional nominations from the floor. In the absence of further nominations, Edwards moved (Adler seconded) to accept the slate as presented. The motion passed unanimously.

Henri Seibert reported that membership in the Society was increasing and that we had more members today than we did at the end of 1975. He requested the membership to provide suggestions for conservation projects to the Chairman of the Conservation Committee, Glenn Stewart. He noted that, pursuant to Board decision, in the future, claims for missing journals would not be honored after three months.

Max Nickerson presented the following resolution:

BE IT RESOLVED that the SSAR wishes to acknowledge Dr. Henri Seibert for his continued outstanding and unselfish efforts on behalf of the SSAR. His performance and dedication serve as a model for those who would strive for excellence on the behalf of the Society. SSAR offers its sincere thanks for a job more than well done.

The resolution was seconded by Kraig Adler and unanimously passed with a standing ovation for Dr. Seibert.

Vial announced the Student Prize for this year would be awarded to Bonnie Walters for her paper entitled "Studies of Interspecific Predation within an Amphibian Community," J. Herp. 9(3): 267-279.

Vial announced that future meetings would be held in 1977 at the University of Kansas, Museum of Natural History; 1978 at Arizona State University, Tempe (in late May or early June); and, in 1979 at the University of Tennessee, Knoxville.

Vial reported that he had charged the Secretary with securing corporate status for the SSAR and submitting application for membership in the Association of Systematics Collections.

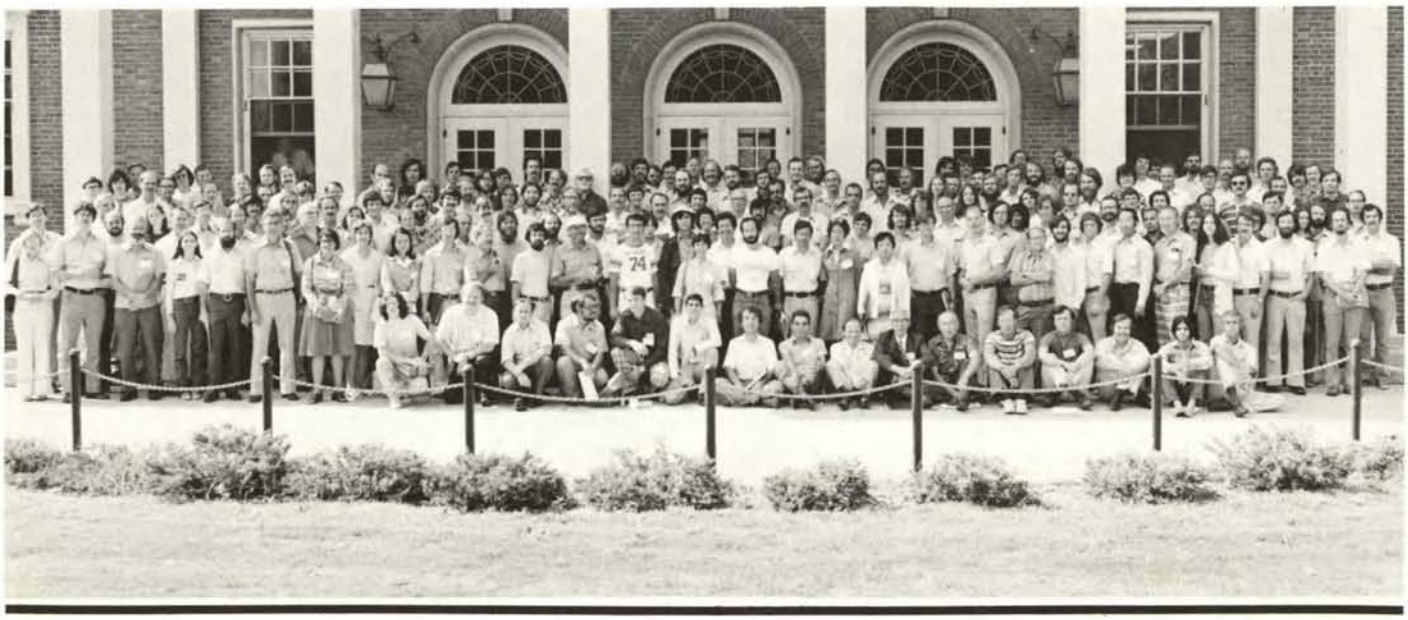
Vial reported that the Journal of Herpetology would receive a one-third increase in its budget for 1977 designed to decrease a backlog of papers awaiting publication and that each issue would therefore be increased in size.

New co-editors had been selected for Herpetological Review effective January 1. The new editors will be Joseph T. Collins and George Pisani. He stated that Collins and Pisani had plans to increase the number of pages published next year by 60-80 pages; further, that the Current Titles section of Herpetological Review was now under the management of Dick Worthington.

Vial stated that fifteen accounts would be published in the Catalogue next year for a subscription price of $6.00.

Kraig Adler reported on the activities of the Facsimile Reprints program noting that McIlhenny's book would be distributed in September or October. Holbrook's volume on North American Herpetology will be available later this fall; 87 patron's copies had been sold. Costs for publishing the Holbrook volume had been met through pre-publication sales. Adler requested that anyone having ideas or suggestions for possible titles that could be published under the Facsimile Reprints program to contact him as soon as possible.

Harry Greene presented the following resolution:



WHEREAS the eastern indigo snake (Drymarchon corais couperi) is a large predator on a variety of vertebrates and therefore of considerable ecological importance; and

WHEREAS the eastern indigo snake is presently found only in portions of the southeastern United States and as such is a relict of an environment that once dominated the coastal plain of North America; and

WHEREAS the eastern indigo snake has declined markedly in southern Georgia recently due to habitat destruction and commercial collecting; and

WHEREAS the legal protection of eastern indigo snakes in Florida is circumvented by alleging that snakes in the pet trade are collected in Georgia;

THEREFORE BE IT RESOLVED that the Society for the Study of Amphibians and Reptiles at its 1976 meeting in Oxford, Ohio expressed unanimous support for Howard Lawler's proposal

of endangered species status for the eastern indigo snake in Georgia; and

BE IT FURTHER RESOLVED that copies of this resolution be forwarded to appropriate authorities in the Department of Natural Resources of the State of Georgia.

Harry Greene moved (Huheey seconded) to accept the resolution as presented. The motion passed unanimously.

Greene presented a second resolution as follows:

WHEREAS the eastern diamondback rattlesnake (Crotalus adamanteus) is a large predator on small mammals and therefore probably of considerable ecological importance; and

WHEREAS rattlesnake populations may be especially vulnerable to disruption because of delayed maturity, small litter size, and biennial reproduction; and

WHEREAS the expressed purposes of these roundups are to promote tourism and control dangerous animals; and

WHEREAS each of these goals could more appropriately be achieved by other methods; and

WHEREAS rattlesnake roundups are often inhumane spectacles and contribute to an unfortunate public image of snakes; and

WHEREAS the use of gas in rattlesnake roundups has potentially lethal side effects on all plants and animals in the vicinity;

THEREFORE BE IT RESOLVED that the Society for the Study of Amphibians and Reptiles at its 1976 meeting in Oxford, Ohio condemns the general practice of rattlesnake roundups and specifically urges restrictions on the introduction of toxic substances into animal burrows during these events;

BE IT FURTHER RESOLVED that copies of this resolution be sent to appropriate state, federal, and private conservation agencies.

Greene moved (Gregory Mayer seconded) to accept the resolution as presented. The resolution passed unanimously.

Bob Mount presented the following resolution:

BE IT RESOLVED that the Conservation Committee be charged with: 1) determining the most appropriate course of action toward the end of amending the Pitman-Robertson Act to permit federal funds appropriated through the Act to be used for research on reptiles and amphibians; and 2) to inaugurate and pursue a program to accomplish that end.

Mount moved (the motion was seconded) to accept the resolution as presented. The motion passed unanimously.

The meeting was adjourned by Jim Vial.

Respectfully submitted,

STEPHEN R. EDWARDS
SSAR Secretary

SYMPOSIUM PARTICIPANTS (Reproductive Biology of Amphibians): 1st Row--Sheldon I. Guttman (Co-Editor Symposium Proceedings), Stephen Tilley, Midori Nishioka, Toshijiro Kawamura, Lynn Houck, Timothy Halliday. 2nd Row--Hans Blankenhorn, Kentwood Wells, Robert Capranica, Giorgio Mancino, Leszek Berger, Murray Littlejohn. 3rd Row: Hans Schneider, Thomas Uzzell, Max Nickerson, Stevan Arnold, Douglas H. Taylor (Co-Editor Symposium Proceedings).

ANOTHER YELLOW ALBINO AMPHIBIAN

This report concerns a yellow albino Fowler's Toad, Bufo woodhousei fowleri, that was captured in Hunt County, near Commerce, Texas during the early part of September, 1975, and which has been kept alive in a terrarium in the Biological Learning Center at East Texas State University.

The term "yellow albino" has been applied previously to a salamander, Desmognathus fuscus, by Channell and Valentine (1972). The color of their salamander is remarkably similar to the coloration of the Fowler's Toad in the East Texas collection.

Conant (1975: 310) describes the normal coloration of Fowler's Toad as follows: "A typical Fowler's Toad has: (a) 3 or more warts in each of the largest dark spots; (b) a virtually unspotted chest and belly... Many speciemns have a single dark breast spot on an otherwise immaculate venter. The general dorsal coloration is brown or gray or, more rarely, greenish or brick-red. A light middorsal stripe."

Max Hensley (1959: 138) reports the capture of a "particularly albinistic female," two undescribed specimens and a "light mutant" of this species. In the specimen from east Texas the pupil is black and the iris is antique gold, with a slight veinous pattern which appears chocolate brown. Head markings are absent. The cranial crests are a gray-bone white. The paratoid glands are pitted and a slightly darker shade of bone white than the cranial crests. This is partly due to a shadow effect caused by the pits. The coloration of the anterior 2/3 of the back region is a slightly lighter tint than the head. A dorsolateral blotch, ochre in color, is present in front of the femoral area. The dorsum is unicolor, without markings such as spots, or a vertebral stripe. A dorsal crease, which is difficult to see in normal specimens, is very evident. This crease extends from the posterior portion of the head to the anal region. The upper portion of the thighs are greenish-yellow. The rest of the leg is the same as the dorsum. The soles of the front feet are a reddish-purple. The tips of the toes are a light salmon color. A moss green coloration is apparent in grooves between the tubercles on the lower leg portions and the dorsum of the hind feet. The soles of the hind feet are bluish-gray, apparently the color of subcutaneous tissue as seen through the translucent integument. Tips of the toes are sienna and bordered by pink. The throat is yellowish-beige and unmarked. The chest and upper regions of the belly are a lighter shade than on the back

while the lower abdominal area exhibits a capillary network which is cadmium red.

The specimen has been maintained in a 18" x 10" terrarium. It has grown very fat on a diet of mealworms (Tenebrio sp.), crickets and June Bugs. During nearly eight months of confinement, the toad's coloration has remained unchanged. It lacks the ability of changing to lighter or darker phases. It seems to follow the typical secretive behavior of toads. Judging from the speed and efficiency of its predatory behavior, the toad has relatively good vision, especially in partial darkness. This is in contrast to data reported for an albino Eumeces fasciatus (Brungs and Britt: 369).

ACKNOWLEDGMENTS

The authors would like to express their gratitude to Dr. Donald Ingold for proofreading the manuscript, to Deborah Malzac of East Texas State University who assisted with color identifications, and to Aletha Vance for typing the final manuscript.

AN ALBINO AMBYSTOMA TIGRINUM MAVORTIUM FROM KANSAS

Albino Ambystoma tigrinum have frequently been reported in the literature (Hensley, 1959; Brame, 1963; Bobrowsky, 1965; Gilboa and Dowling, 1974), but albinos of the subspecies A.t. mavortium apparently are uncommon.

Bragg (1955) and Black (1969) have reported white larvae of the Barred Tiger Salamander in western Oklahoma, but this coloration was apparently due to the physical and chemical conditions in the environment.

An albino Barred Tiger Salamander was obtained from Alan L. Maughan, a student at Oklahoma Baptist University, who obtained it from his grandfather, W.V. Heimey, of Miniola, Clark Co., Kansas. A Miniola water meter reader found the albino salamander in a meter box in November, 1974. Mr. Heimey uses the tiger salamanders for fishing bait; this was the second albino salamander obtained in this manner within the past three years.

The albino salamander (Figure 1), apparently a female, has pink eyes. Its yellow barred markings are in sharp contrast to the ground color. The skin is translucent giving a ground color of light gray beige with an overall rosy cast. The rosy cast is more evident in the costal grooves. The ground color is progressively lighter towards and onto the tail where it is grayish white. The belly skin is also translucent with darker viscera and parts of the circulatory system visible.

Following the methods of measurement in Peters (1964), the female has the following live measurements: Total length, 181.0 mm; Total length 1: 76.0; Head-body length 1: 105.0 mm; Axilla-groin length, 53.0 mm; Head length, 25.0 mm.

The salamander is on exhibit at the Oklahoma City Zoo.

OBSERVATIONS ON THE FOOD OF THREE FOREST-DWELLING LIZARDS IN CALIFORNIA

Few observations have been reported on the arboreal habits of lizards in western North America (Cunningham, 1955) and little is known about the diet of temperate forest-dwelling lizards (Johnson, 1965; Stebbins, 1966). An exception is the work of Toliver and Jennings (1975) who have studied the predatory role of Sceloporus undulatus tristichus Cope on a tip moth which attacks ponderosa pine (Pinus ponderosa Lawson). Data reported here are part of a study of the vertebrate predators of the western pine beetle, Dendroctonus brevicomis Le Conte, in California. Information presented adds to the scant knowledge on food habits of forest lizards.

The study was conducted at three locations in California: Blodgett Research Forest, Challenge, and McCloud Flat. The Blodgett Research Forest is located 16 km northwest of Georgetown, El Dorado County, at an elevation of between 1,250 and 1,310 m. The forest is a mixed conifer type, predominantly second growth stand of ponderosa pine (Pinus ponderosa Lawson), white fir (Abies concolor [Gordon and Glendenning] Lindley), and incense cedar (Libocedrus decurrens Torrey). Although considerable scattered old growth pine and fir remains, most of the trees are between 50 and 80 years old. At Challenge, Yuba County, the elevation varies from 760 to 910 m with the scattered ponderosa pine stand varying in age between 25 and 200 years. McCloud Flat, in the Shasta Trinity Forest, Siskiyou County, is located at an elevation of 1,160 m and the forest is a 100-year-old ponderosa pine stand intermixed with a few incense cedar. Five northern alligator lizards (Gerrhonotus coeruleus Wiegmann), three sagebrush lizards (Sceloporus graciosus Baird and Girard) and one western fence lizard (S. occidentalis Baird and Girard) were collected during July and August 1966 and 1967 at Gaddis Creek in Blodgett Research Forest. One northern alligator lizard and one western fence lizard were collected, at each of two locations (McCloud Flat and Challenge). The stomach of each lizard was removed, immediately after collection, and stored in 70% ethanol along with the carcass until examination.

Stomach contents were spread out uniformly to about 1 mm thickness in a petri dish with a millimeter grid underneath. Identification of the contents to taxonomic category proceeded as far as the stage of digestion permitted. Food particles were counted and the percent volume of each taxon was estimated from the area occupied by each taxon in relation to the entire stomach contents.

The stomach analysis is summarized below.

Although all three species of lizards are known to climb over wood piles and tree trunks (Stebbins, 1954; 1966), I seldom observed them on standing trees. Lizards were usually not more than 0.5 m from the ground and were neither on the trees under attack nor on those from which bark beetles were emerging. Of the two genera, Gerrhonotus was seen less frequently on standing trees than Sceloporus.

I wish to express my gratitude to Dr. R.W. Stark, University of Idaho, formerly University of California, Berkeley, for his encouragement during the study, and Dr. R.C. Stebbins, University of California, Berkeley, for the identification of the lizards. The investigations were supported in part by grants from the National Science Foundation (G-21004), T. B. Walker and Surdna Foundations, and the Canadian National Research Council through its Graduate Fellowship program.

All SSAR Members--Please Note

Effective immediately, Douglas H. Taylor (Department of Zoology, Miami University, Oxford, Ohio 45056) assumes the position of SSAR Publications Secretary. All requests and orders for SSAR publications and back issues should be sent to Dr. Taylor. Do not send them to Henri Seibert, SSAR Treasurer, or your order may be delayed for some time.

Change of Address Notification

We want to remind our members that the Journal of Herpetology, Herpetological Review, and the Catalogue of American Amphibians and Reptiles are mailed as Bulk Rate material and as such, can not be forwarded. That is, leaving a forwarding address at the Post Office or at the last place of your residence will not enable these publications to be sent on. It was decided by the Board of Directors at the last Annual Meeting that the SSAR, as of January 1, will no longer replace free of charge copies lost because of address changes unless notification of such change is received prior to the issuance of mailing labels to our distributors. It is therefore imperative that you provide us with your new address immediately. It is only with your cooperation that we can hope to maintain our dues structure as low as possible.

Henri C. Seibert
SSAR Treasurer

SSAR Member Support Strong

The SSAR is again happy to thank the following members (124 of them) for their financial contributions. This more than 10% participation also indicates enthusiastic approbation of SSAR endeavors.

In Memoriam

BERTHA LUTZ
NATURALIST-FEMINIST (1894-1976)

The distinguished Brazilian naturalist-feminist, Bertha Lutz, died in Rio de Janeiro on 16 September 1976. She was one of two children born to Dr. Aldolpho Lutz and Amy Chesshyre Fowler. Her coffin was borne entirely by women to the family tomb in Rio de Janeiro, where her parents and brother are buried. She was a life-long advocate of women's rights. Her rich family heritage prepared her well to pursue a diversity of interests.

The Lutz family is surely among the most distinguished in the annals of the Brazilian nation. Her father was of Swiss parentage. The Lutz family name has been on the register of the Burger of Bern, Switzerland, since 1559. Dr. Adolpho Lutz was born in Rio de Janeiro. He was a physician naturalist who made such significant contributions to the study of tropical medicine, natural history and government service that in 1955 the Brazilian government commemorated the centennial of his birth. His effigy has appeared on Brazilian postal stamps; several streets have been named after him. He married Amy Chesshyre Fowler in Honolulu. Dr. A. Lutz was conducting research on leprosy and had gone to Hawaii to pursue that interest. Amy Fowler, an Englishwoman, was a follower of Florence Nightingale. She had gone to Hawaii as a volunteer nurse to the lepers. Later she established the first free school in Brazil for neglected boys. She and Dr. Lutz returned to Brazil in 1893 after spending several months in San Francisco.

Bertha Lutz was born in Sao Paulo on 2 August 1894. She attended the secondary school in Sao Paulo, the Sorbonne, University of Paris and studied law at the Federal University of Rio de Janeiro.

Two major aspects of her life may be briefly recounted. First, she was a highly respected naturalist who published on a wide range of subjects. Her primary research was the study of frogs, but she authored papers on botany and general natural history, such as "Wild Life in Brazil" which appeared in Natural History in 1932. Her studies of frogs are usually indicative of her emphasis on field and laboratory observation. For many years she maintained a small live collection of frogs. Among her well illustrated field observations are accounts of the fighting behavior of Hyla faber (1960, Copeia, 61-63) and the nest building of Hyla pardalis (1960, Copeia, 364-366). Many of her publications are illustrated with photographs by her brother Professor Gualter A. Lutz. She was greatly interested in anuran life histories, behavior and ontogenetic development. "Trends Towards Non-Aquatic and Direct Development in Frogs" (1947, Copeia, 242-252) and the recent "Geographical and Ecological Notes on Cisandine to Platine Frogs" (1972, Journal of Herpetology 6: 83-100) are two of her memorable attempts at synthesis.

She described several new taxa and often provided descriptions of little known forms of Brazilian frogs. Her book Brazilian Species of Hyla, published in 1973, was to be the first of several books presenting observations on Brazilian frogs that she had gathered over several decades of work in the field and in the laboratory. The study of frogs began as a family effort under the direction of her father. She became interested in frogs at a young age when she accompanied her father on collecting trips. Fortunately, for herpetology, it proved to be a life long interest.

Bertha Lutz (1894-1976)

Second, but no less distinguished than her scientific career, are her considerable achievements as a feminist. As a teenager she became interested in women's suffrage and later took a law degree to prepare her for the legal advancement of women's rights. She authored papers on legal topics. Interestingly, she discovered no antifeminism statutes in Brazil. It was simply that women had not voted or held government positions in Brazil because no leader had ever told them they could. Working with a small group of women in 1922, she helped to organize the first women's rights association in Brazil--the Federacao Brasileira pelo Progresso Feminino. This organization was largely responsible for securing equal suffrage in 1933 and has subsequently achieved much in the women's movement. It is active today. In 1932, Bertha Lutz was on the committee charged to draft a new constitution for Brazil. Her efforts were evident when in 1934 Brazil included a women's rights provision in its new constitution. With the aid of government officials she introduced and passed bills to insure women's rights in the labor movement. She was repeatedly appointed and elected to important positions from which she expressed the need for equal rights for women. She often was the official representative of the Brazilian government at international conferences. She represented Brazil at the International Conference of Women in Rome (1923); Berlin (1929); and at the Pan-American Conference of Women in Baltimore (1922); Washington (1925). She was a delegate to the 7th Pan-American Conference, Montevideo (1933); a member of the Committee on labor conditions of women of the International Bureau of the League of Nations. She was a delegate to the United Nations Conference in San Francisco in 1945. In 1974, she was Brazil's representative on the Inter-American Commission for Women, Organization of American States, which convened in Washington, D.C. Her career in government service and science was often complementary. In fact, her successful competition for the position of secretary of the National Museum in Rio de Janeiro was an achievement for women by which she became the second woman to hold an important post in government service. In 1931 she became head of the department of natural history and geology and acting head of the department of botany of the National Museum. Her contributions to agriculture earned her decorations from the Belgian (1924) and German (1931) governments.

She lived in a large house in Rio de Janeiro on the Avenida Edison Passos, until shortly before her death. She also maintained a small rural cottage in Teresopolis. Localities near the latter are sometimes referred to in her publications as sites of some of her field observations. She was fond of dogs and kept four of them as pets. One day, during her visit to my home in Houston, we went to the Big Thicket. It was an active and energetic day but she thoroughly enjoyed it. She was 80 years of age at that time.

The Bertha Lutz (Fig. 1) that I knew was a highly cultured and gentle woman. Those who value human rights and the lives of frogs have little more for their pleasure because of her.

J. P. KENNEDY, Graduate School of Biomedical Sciences, University of Texas, Houston, Texas 77025.

ISABELLE HUNT CONANT (1901-1976)

Most, if not all, of those persons who have an interest in the amphibians and reptiles of the United States are aware of Isabelle Hunt Conant as the creator of the many excellent illustrations in Roger Conant's Field Guide to the Reptiles and Amphibians of Eastern and Central North America. Her skill as a photographer and artist is evident even in a casual riffling through the book.

Less evident, to those who did not know Isabelle and without some thought, is the tremendous amount of work involved in the production of these illustrations. Behind the many hours of painstaking photography, print-making and hand-coloring was the obsessive desire of a master craftswoman to achieve the best possible results from her talents. This kind of dedication and self-discipline were characteristics of Isabelle that, at those times of frustration periodic to all artists, may have been severely tested but never were defeated.

Taking the easy way out was not Isabelle's style...to always strive for the best, was. Her success as an animal photographer at both the Staten Island and Philadelphia Zoos led to continuous requests for her photographs from around the world; and even from local press photographers who sought her assistance in fulfilling an assignment. Beyond this professional recognition Isabelle contributed innumerable illustrations of amphibians and reptiles to scientists for use in the technical publications reporting upon their studies. No piece of work carrying her credit line was ever less than Isabelle's best effort.

Isabelle Hunt Conant was the loyal supporter of her husband, Dr. Roger Conant, through his tenure as Public Relations Director and as Director of the Philadelphia Zoological Garden; indeed, in all his activities. She was his constant companion and aide on a long series of field trips that took them throughout Mexico, where camping-out was the only way to ensure a successful collecting trip. Isabelle and Roger Conant attended many herpetological and zoo conventions throughout the United States, in Europe and in Africa. Her camera, on all trips, always was in ready reach and many beautiful and exciting photographs were the expected result.

The extensive files of negatives and slides accumulated during her professional career might indicate that Isabelle was all work. Not so. She enjoyed social contacts with groups large and small and her company, in turn, always was enjoyable. Isabelle's excitement about her activities, whether achieving a handsome photograph, enjoying an evening of jazz, Dixieland style, or preparing jars of tasty (a personal recipe) cranberry preserves to enhance the Christmas dinners of friends, will be remembered fondly and warmly by many. All who knew Isabelle, in herpetological and zoo circles here and abroad, admired her work and both enjoyed and benefited by her friendship. Isabelle Hunt Conant was a fine craftswoman and a good and loyal friend.

EDMUND V. MALNATE, Academy of Natural Sciences, Philadelphia, Pennsylvania 19103.

This photograph of two baby caimen was taken by Isabelle Hunt Conant on 29 March 1947 at the Philadelphia Zoo. It took first prize in the Nature Division competition of the Photographic Society of America, and was one of Isabelle Conant's favorite photographs.

Conservation

SUPPORT GALAPAGOS PROGRAM

In 1959, just one hundred years after the appearance of Darwin's famous work, the Charles Darwin Foundation for the Galapagos Isles was founded under the auspices of UNESCO and the IUCN as an international organization devoted to the conservation and study of the natural history of the Galapagos. The Darwin Foundation was entrusted by the Government with the establishment of a permanent field station in the Islands which was officially inaugurated in 1964 and has continued to grow in size and responsibility.

During the first years (1960 - 1964), work was mainly concentrated on surveys of endangered species and establishing the research station. Basic data were obtained to design conservation projects, and many scientific missions, financed by their home institutes or countries, began coming to the station. The second period (1965-1968) commenced with more specific conservation measures, (e.g. rearing of tortoises), and educational programs (e.g. natural history courses for Galapagos teachers). The third period (1968-1976) has shown a substantial increase in practical conservation measures (tortoise rearing programs, control and extermination of introduced animals, tourist management programs), environmental education projects, research on endangered species and habitats, and the establishment and rapid growth of the Galapagos National Park Service.

Native plants, animals and habitats continue to be severely threatened on almost all of the islands by introduced predators and competitors (pigs, dogs, cats, black rats, goats, donkeys, cattle), many exotic plants, and several invertebrates (including a fireant). More tourists have visited the Galapagos in the 1970's than in all previous decades. These concentrations of visitors in the most beautiful and representative sites in the Islands must be controlled carefully and their impact studied for future planning.

The nontourist population of the Galapagos has nearly tripled since 1960 and now numbers approximately 4,000.

Increased deployment of Ecuadorian wardens and patrol boats, expansion of the educational programs, and an increase in applied research on introduced animals and plants and tourist impact are needed. The normal scientific work of the Station must be continued along with the vital conservation programs.

All this requires money.

Over 90% of the income must come from personal donations to the Foundation or to the World Wildlife Fund, the Frankfurt Zoologische Gesellschaft or similar supporters. Since to such a large extent the income depends on irregular sources, a gift is so important.

Contributions to the Foundation are tax deductible in certain countries, and will be very gratefully received at the Darwin Station or through the offices of the Foundation listed below. All contributions receive Noticias de Galapagos, our journal carrying articles on Galapagos science and conservation as well as news from the Darwin Station about current events in the Islands.

Secretary-General
Charles Darwin Foundation
Palais de Academies
1, rue Ducale
Brussels 1, BELGIUM

Secretary for the Americas
Charles Darwin Foundation
c/o Smithsonian Institution
Washington, D.C. 20560, USA

Please note that tax deductions for U.S. citizens are permitted only on gifts to non-profit U.S. institutions. U.S. contributors can make checks payable to the Smithsonian Institution "for conservation and science in the Galapagos Islands" and send them to the Foundation's Secretary for the Americas (see above address), or similarly may make tax - deductible donations through the World Wildlife Fund.

NEWSLETTER OF THE MADRAS SNAKE PARK TRUST

The Madras Snake Park and Conservation Centre of Madras, India, has recently issued the first issue of their newsletter to be issued at an irregular basis, three or four times a year.

Mrs. Zahida Whitaker edits this interesting publication intended to create and further interest in Indian Reptiles and Amphibians.

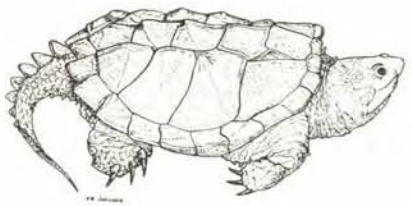
The Madras Snake Park was initiated and founded by Romulus Whitaker (Honorary Director) in 1969 with financial help from World Wildlife Fund. The Park is a private organization and is self supporting on an entrance charge of 25 paise. About 500 snakes are housed in open "pits" and terrariums. Apart from being a public education center, the Park undertakes and encourages research on Indian herpetofauna. Over half a million people visit the Park each year.

In 1975, a crocodile breeding project, the Madras Crocodile Bank, was started for the breeding and Indian Crocodilians (Crocodylus palustris, Crocodylus porusus, and Gavialis gangeticus) all of which have shown an alarming decline in number due to poaching, habitat destruction, etc. The World Wildlife Fund has donated Rs. 10,000 to this project. Due to paucity of funds, opening of the Crocodile Bank has been delayed.

If you are interested in helping this project and receiving their Newsletter, write to:

Mrs. Zahida Whitaker, Editor Newsletter, Madras Snake Park, Guindy Deer Park, Madras 600022, India.

Enclose a small donation to help them defray cost of printing and mailing this overseas. This is the type of conservation project that actually is doing something concrete about preserving the endangered wildlife in a critical situation. Rom is a sincere young man and has been working hard with little recognition for several years to save and preserve the herpetofauna of India.



PROPOSED ENDANGERED SPECIES

The USDI Office of Endangered Species (Washington, D.C. 20240) has information on file that the giant anole, Anolis roosevelti, and the St. Croix ground lizard, Ameiva poloops, should be determined to be Endangered. On January 10, 1977, they published in the Federal Register (42 FR 2101-2102 and 2102-2104) their proposal to make such a determination.

Information you might provide would be helpful in this decision and they would particularly appreciate you: 1) providing any factual data you may have access to concerning the status of this species; 2) informing them of any special considerations that should be taken into account prior to their final determination of the lizard's status; 3) providing them with additional habitat areas which may be critical to the species; or 4) providing any other information you feel relevant.

The Office of Endangered Species is proposing to determine Critical Habitat (pursuant to Section 7 of the Endangered Species Act) for the species at this time, and are soliciting information concerning the location of additional areas which should be designated as Critical Habitat for the giant anole. Such habitat information is particularly desirable. Reply with reference to FWS/OES/P33 (Ameiva) and/or FWS/OES/P37 (Anolis).

Book Reviews

SALT GLANDS IN BIRDS AND REPTILES (Monographs of the Physiological Society 32) by M. Peaker and J. L. Linzell. Cambridge University Press, New York and London. x + 307 pp., illus. $27.50.

The function of salt glands was first described for birds in 1957 and for marine reptiles the following year. Since then research on these glands has progressed until our knowledge can fill this 300-page monograph. Its first 227 pages are devoted to the anatomy and physiology of avian salt glands whereas only 38 pages are devoted to the reptilian glands.

Although the reptilian section is much the shorter (a reflection of research interests? or difficulty of subjects?) it is potentially the more interesting as reptiles possess a variety of salt secreting glands, none of which is homologous to its avian counterpart. Marine turtles and Malaclemys have orbital (lachrymal) glands that secrete sodium ions, sea snakes have oral (sublingual) glands, and lizards have nasal glands that secrete potassium, in the terrestrial species, as well as sodium. Salt water crocodiles have (lachrymal?) glands but no gland has yet been detected in the tuatara. Although the phylogeny and evolutionary implications of the glands are discussed in the terminal chapter, it is obvious that the reptiles need more intensive research to answer a host of questions dealing with origin, adaptiveness, as well as basic physiology.

In true monographic spirit, the book has an extensive bibliography with an addendum of more recent work, an author and subject index, plus useful figures, plates and tables. It is also most readable.

THE PALEARCTIC DESERT LIZARDS by Dr. N. N. Scherbak. 296 pp., 92 photos. Published by The Academy of Sciences Ukrainien SSR Institute of Zoology, Kiev, USSR. 1974.

This book by Nicolay Scherbak (Curator of Kiev Zoological Museum) is his doctoral dissertation work on Asiatic lizards of the genus Eremias. The revision covers 22 species and 36 subspecies previously assigned to this genus and is the result of 5 years of research in the field and laboratory using or observing approximately 5000 lizards from the author's personal collection, the collections of European Museums, and from collections in the USA (California). These desert lizards are particularly distributed in the USSR (Asiatic area), Central Asia, and Mongolia, and are difficult to identify and differentiate due to extensive variation. On the basis of studying many populations and a thorough knowledge of literature about the genus, the author writes that constructing an absolutely reliable identification table of the genus Eremias is practically impossible. The author's system of identification has a 95% reliability in identifying these variable lizards. Scherbak's definition of the Asiatic group now includes 26 species and 5 subgenera: Eremias, Pareremias, Omnateremias, Rhabderemias, and Scapteira. Eremias strauchi, E. persica, E. regeli and some other forms are described as species, not subspecies as is the opinion of some herpetologists (R. Mertens, S. Minton, and others). According to the author's experience, the identification of species of Eremias by histological methods is difficult. The species Eremias guttulata (according to Scherbak) is a member of the African desert lizard genus Mesalina containing the following species: Mesalina guttulata, M. olivieri, M. brevirostris, M. adramitana, M. rubropunctata, M. pasteuri, M. breviceps, M. managuensis, M. undata, M. benguelensis, M. laticeps, M. furschelli, and M. lineo-occellata. Ecological observations are most detailed about feeding (including feeding tables), observed activity by author (about 12 species of 22 populations), behavior in captivity, temperature regime from observations in the field and laboratory on 13 specimens, and geographic variability. Each species description contains photos of typical specimens, synonymys, and a literature list. The author includes his original research on Mongolian desert lizards, especially information on livebearing, feeding, and activity in E. przewalskii. This book is especially interesting and useful to zoologists, herpetologists, and museum curators, as systematic monograph about Asiatic desert lizards of the genus Eremias.

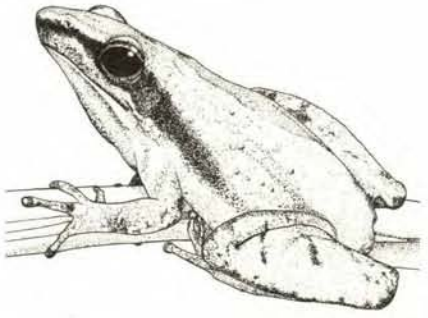
George Mamonov
Artema Street, 74-3
252059 Kiev 59
U.S.S.R.

EDITOR'S NOTE: Mr. Mamonov is willing to exchange books and reprints (including the title reviewed above) written by Russian herpetologists in order to obtain an SSAR membership in his name. Anyone interested in such an exchange should make arrangements with Mr. Mamonov and the SSAR Treasurer (see inside cover for address).

NEPALESE FROGS: THE SUBGENUS IN HERPETOLOGICAL CLASSIFICATION. Les Grenouilles du Sous-genre Paa du Nepal. Famille Ranidae, Genre Rana, by Alain Dubois. Cahiers Nepalais--Documents No. 6. vi + 275 pp., 1976. ISBN 2.222.01940.0. Centre National de la Recherche Scientifique, 15 quai Anatole - France 75700 Paris. Price 25 French Francs.

This paper-bound publication offset from typescript on pages trimmed to 20.5 X 29.5 cm is Dubois' doctoral disseration, completed under the direction of Prof. Maxime Lamotte at l'Ecole Normal Superieure in Paris. The subject of the book is the "Rana liebigii group," which was recognized as the subgenus Paa by Dubois (1975).

The introductory material (21 pages) contains a geographical and phytogeographic review of Nepal and a geographic analysis of the amphibians of this Himalayan country. Dubois records one species of salamander and 37 species of frogs in the Nepalese herpetofauna; 21 of these species are members of the genus Rana (sensu lato). Much of the material was collected by Dubois between 1970 and 1973. The following section of eight pages is devoted to the definition of the subgenus Paa and the justification of the recognition of 19 species as a subgenus.



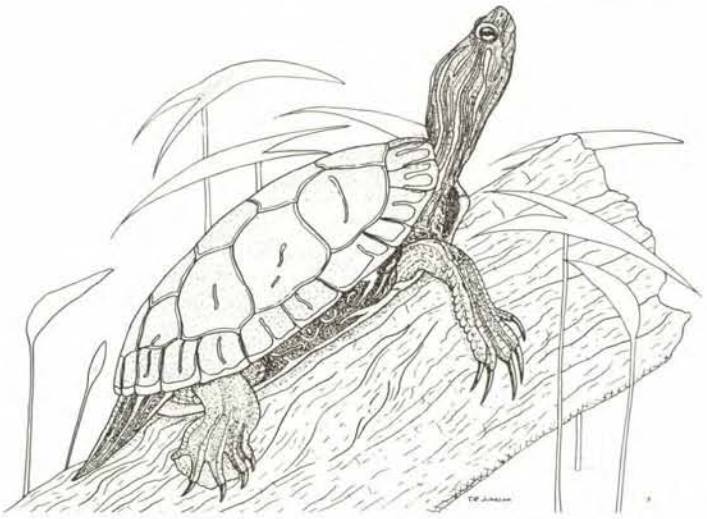
In sections on the Paa of Nepal, the first 11 pages are devoted to the materials and methods of study. The bulk of the book (168 pages) contains the eight species of Paa known from Nepal. Each of the species accounts contains detailed descriptions of adults and larvae and discussions of sexual dimorphism, reproduction, behavior, ecology, distribution, and in some species ethnozoology. A concluding section of 28 pages contains various univariate statistical analyses of the Nepalese species of Paa and "phyletic" arrangements, which are cluster diagrams based solely on phenetics.

Appendices contain 38 tables, a list of localities, and a list of specimens examined. The text contains 59 tables and 92 figures--maps, graphs, and line drawings of frogs.

Dubois' work is a seemingly thorough and comprehensive review of a formerly poorly known group of frogs in a region that until recent years has been unknown to the biologist. Dubois' systematic approach offers nothing novel; in fact, his phenetic approach leaves him open for criticism. The most noteworthy aspect of Dubois' monograph is his formal recognition of a group of species as a subgenus.

Subgenera have been used sparingly in herpetology, although their use is more frequent and accepted in mammalogy and ichthyology. The appearance of a monograph dealing with a subgenus of frogs is bound to evoke responses varying from enthusiastic support to outright rejection. A negative response is expected from most herpetologists who deal with North American amphibians and reptiles, for literature on the North American herpetofauna is almost devoid of the subgenus. In recent years only the sporadic use of the subgenera Spea and Scaphiopus occurs in the literature.

Systematists have been struggling for decades with the problem of imposing a static classification on a dynamic evolutionary system. Recent attempts at improving the objectivity of the reconstruction of phylogenies (Hennig, 1966), have raised new problems in classification. The definition of branching sequences and sister groups on the basis of shared derived characters frequently results in cladograms at variance with present classification and the necessity of resurrecting old, or coining new, names for separate clades. Heyer and Liem's (1976) analysis of myobatrachid frogs necessitated the recognition of additional genera and subfamilies. Refinements of phylogenies and efforts to have classifications reflect the phylogenies of the organisms have resulted in greater use of optional heirarchical categories, such as subfamilies and tribes. These categories have been used effectively in plethodontid salamanders (Wake, 1966) and leptodactylid frogs (Lynch, 1971).



The generic category, although ideally reflecting a natural grouping of species on the basis of morphology, ecology, and geography (Inger, 1954), too often is a category of convenience. Very large genera are burdensome and to some systematists completely unpalatable. Rana with about 280 species, Hyla with about 300 species, and Eleutherodactylus with about 340 species are among the largest anuran genera, whereas Anolis is a notoriously large reptilian genus. Etheridge (1960) treated the two major groups of Anolis as the alpha and beta sections of the genus; these informal groups have become so well entrenched in the herpetological literature that Savage's (1973) resurrection of the generic name Norops for one of the groups has been ignored in favor of the accepted group designations. The recognition of infrageneric groupings as species groups is a common practice (Zweifel, 1959; Duellman, 1970; Wake and Lynch, 1976). In treating the immense genus Eleutherodactylus, Lynch (1976) recognized numerically designed infrageneric units, each containing species groups.

The use of subgenera presents problems not encountered with other optional heirarchical categories. The principal problem is nomenclatural, because a name whether proposed or used as a generic or subgeneric name is a genus group name under the International Rules of Zoological Nomenclature and is subject to all of the applicable rules. Thus, using one of Dubois' group as an example, all three of the following combinations are nomenclaturally correct:

1. Rana liebigii
2. Rana (Paa) liebigii
3. Paa liebigii

The subgeneric name Paa will be used knowingly or unwittingly as a full generic name within the next few years. Presumably if the author of that combination does so knowingly, it is indicative of the elevation of Paa to a classificatory and evolutionary rank equal to Rana. At the present time there is lack of uniformity of usage of genus group names in Old World ranids. For example, Dubois (1976:12) recognizes Dicroglossus, Hylarana, and Tomopterna as subgenera of Rana, but these are accorded full generic rank by Laurent (1964) and Perrett (1966).

Vacillation in the level of usage of genus group names creates problems for the systematist and nightmares for the non-systematist. Persons compiling distributional checklists or files for environmental impact statements working from the literature will not associate Rana liebigii and Paa liebigii, although they might make the association if the combination Rana (Paa) liebigii also were included. Computer compilation most likely would result in the recognition of three taxa. Such nomenclatural confusion detracts from the credibility of taxonomy.

These problems can be eliminated by the use of informal terms instead of formal nomenclatural designations of subgeneric units. Thus, the designation "Rana liebigii group" denotes a group of species of Rana that are more alike (closely related ?) than any one member of that group is to other Rana. The phylogenetic information is evident without cluttering the classification. On the other hand, if members of the group can be shown to be of monophyletic origin and to have reached an evolutionary differentiation equal to that of the genus in which they have been placed, they should be accorded full generic recognition. On this philosophical basis, the subgenus is an unnecessary and undesirable category.

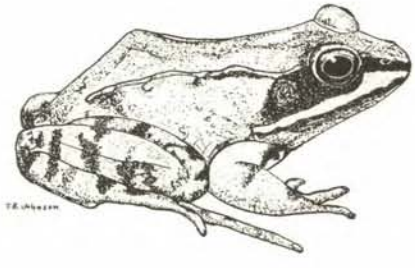
Geographic Distribution

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same. The standard format for a geographic distribution record is:

Scientific name (common name) as it appears in Conant (1956, 1975) or Stebbins (1966). Locality (use metric for distances). Date and collector(s). Identified or verfied by. Place of deposition and catalogue number. Comments. Citation. Submitted by (give name and address).

Please submit new geographic distribution records in the standard format only to Joseph C. Mitchell, Graduate Program in Ecology, University of Tennessee, Knoxville, Tennessee 37916. Short manuscripts are acceptable when data cannot be adequately presented in the standard format.

Recommended citation for new geographic distribution records appearing in Herpetological Review is: Jones, J. 1977. Geographic distribution: Rana pipiens. SSAR Herp. Review 8(1): 1.



CAUDATA (SALAMANDERS)

AMBYSTOMA TREMBLAYI (Tremblay's salamander). USA. WISCONSIN: Florence Co: 10 km E Newald. 24 April 1976. Ellen Dohr. MICHIGAN: Gogebic Co: 6.6 km E Marenisco (2 spec). 29 May 1976. Chris Rogers. MICHIGAN: Gogebic Co: 8.8 km SSW Watersmeet. 30 May 1976. Jeffrey Briggs. Erythrocyte confirmed. Milwaukee Public Museum 13226-13229 respectively. Extends known range through NE Wisconsin into W Michigan upper peninsula. (Conant, 1975, A Field Guide to Reptiles and Amphibians of Eastern and Central North America, Houghton Mifflin Co., Boston). Submitted by Jeffrey L. Briggs, Department of Zoology, University of Wisconsin, Milwaukee, Wisconsin 53201.

SALIENTIA (FROGS AND TOADS)

HYLA CRUCIFER (Spring peeper). USA. SOUTH DAKOTA: Bon Homme Co: Springfield. 28 June 1924. E. C. O'Roke. Verified by Stephen D. Busack and George R. Zug, National Museum of Natural History. USNM 68719. First record for the state (Fishbeck and Underhill, 1959, Proc. South Dakota Acad. Sci. 38: 107-113, and Conant, 1975, A Field Guide to Reptiles and Amphibians of Eastern and Central North America, Houghton Mifflin Co; Boston). Submitted by Stephen D. Busack, National Fish and Wildlife Lab, USFWS, National Museum of Natural History, Washington, D.C. 20560.

RANA SYLVATICA (Wood frog). USA. ARKANSAS: Independence Co: 4.8 km W Ark. Rt. 167, E Chinn Springs. 17 June 1968. N. H. Douglas et al. Northeast Louisiana University, NLU 18678. ARKANSAS: Independence Co: Adler Cave. 1 August 1970. D.H. White. NLU 31036. New county record and extends range of isolated records within the state from northwest (Dowling, 1956, Occ. Papers Univ. Arkansas Mus. 19) and central Ozarks (Schuier et al., 1972, Proc. Arkansas Acad. Sci. 26: 61-66) 56.8 km to the eastern border of the Interior Highlands province. Submitted by Henry W. Robison, Department of Biological Sciences, Southern Arkansas University, Magnolia, Arkansas 71753, and Neil H. Douglas, Department of Biology, Northeast Louisiana University, Monroe, Louisiana 71201.

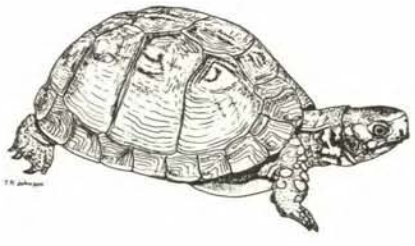
SAURIA (LIZARDS)

IGUANA IGUANA (Common green iguana). USA. GREATER ANTILLES: Puerto Rican Bank, La Cordillera, Cayo Icacos, 1.5 km ENE Soroco, Puerto Rico, 5 m 313v., 18 23N, 16 23W. 5 January 1976. S.D. Garber and J. Moreno. Specimen alive in collection of S.D. Garber. First voucher specimen from Greater Antilles and outer islands. Westward extension of 20 km from its known range on many islands and cays of the Virgin Islands (Schwartz and Thomas, 1975, Carnegie Mus. Spec. Pub. 1: 1-216). Seven individuals observed (4 adults, 3 juveniles). Of the adults (one of which is in the author's collection), the tubercles on the nape, snout squamation, lack of dorsal pattern, and pronounced ventral pattern concur with significant clinal characters that occur in the northwestern Lesser Antilles (Lazell, 1973, Bull. Mus. Comp. Zool. 143). Submitted by S.D. Garber, Department of Natural Resources, Cornell University, Ithaca, New York 14853.

SERPENTES (SNAKES)

ARIZONA ELEGANS ELEGANS (Kansas Glossy Snake). USA. OKLAHOMA: Cimarron Co: 16 km E and 11 km S Kenton, and 8 km E Kenton. 19 August 1976. K.L. Soltesz. Verified by H. M. Smith. University of Oklahoma Museum of Zoology, UOMZ 34829-34830. First records for Cimarron County, and supplements Webb (1970, Reptiles of Oklahoma, Univ. Oklahoma Press). Submitted by Kenneth L. Soltesz, Denver Zoological Gardens, Denver, Colorado 80205.

MASTICOPHIS TAENIATUS TAENIATUS (Desert striped whipsnake). USA. COLORADO. Delta Co: 23 km WSW Delta (Capt. H.A. Smith Cabin, 2.4 km NE jct Escalante Canon road and Delta-Montrose county line), 1615 m elev. 15 May 1975. R.L. Holland, B. Evans, and M. Henry. Verified by R.L. Holland, University of Colorado Museum, UCM 51308. First record for the county, and extends range into the Gunnison River drainage (H.M. Smith, pers. comm.). Submitted by Richard L. Holland, Boulder High School, Boulder, Colorado 80302.



NATRIX CYCLOPION CYCLOPION X FLORIDANA (Green water snake). USA. ALABAMA: Baldwin Co: Gulf State Park, Gulf Shores. 1 October 1976. W.E. Cooper and G. Behrens. Auburn University at Montgomery, uncataloged. The specimen was captured at the boundary recorded between N.c. cyclopion and N.c. floridana (Conant, 1975, A Field Guide to Reptiles and Amphibians of Eastern and Central North America, Houghton Mifflin Co., Boston). Although Goff (1936, Occ. Papers Mus. Zool. Univ. Michigan 237: 1-11) predicted that intergrades would be found between Mobile, Alabama, and Leon County, Florida, he was unable to find evidence of intergradation. However, Mount (1975, The reptiles and amphibians of Alabama, Auburn Univ. Agric. Exp. Sta. Pub. Alabama) reported that a slight darkening of the venter in specimens from southeastern Baldwin County. In other respects, the specimens were typical of N.c. floridana. The specimen noted here is also similar to typical N.c. floridana except for its ventral coloration. Both subspecies have a plain white to yellow coloration on the anterior third of the venter. In N.c. cyclopion the plain color gives way to a brown to gray pigment with light half-moons or spots. The venter of N.c. floridana is plain or nearly so except for the subcaudals, which show the dark pigment with light half-moons, as in N.c. cyclopion. The specimen reported herein has a yellowish anterior venter which rapidly gives way to darker pigmentation posteriorly. However, distinct half-moons do not appear until just anterior to the anus. The appearance of this specimen and

those reported by Mount suggest that there is intergradation between the two subspecies in the region predicted by Goff. Intensive collections in this area will be required to establish the geographic and meristic extents of intergradation. Submitted by William E. Cooper, Jr., Department of Biology, Auburn University at Montgomery, Montgomery, Alabama 36109.

TANTILLA NIGRICEPS NIGRICEPS (Plains black-headed snake). USA. COLORADO: Lincoln Co: 2.5 km E and 2 km S Karval. 22 May 1976. J.D. Holmes. Verified by H.M. Smith. University of Colorado Museum, UCM 51484. First record for Lincoln County. Submitted by Kenneth L. Soltesz, Denver Zoological Gardens, Denver, Colorado 80205, and Jeffrey D. Holmes, Air Academy High School, USAF Academy, Colorado Springs, Colorado 80840.

TROPIDOCLONION LINEATUM (Lined snake). USA. OKLAHOMA: Cimarron Co: Carl Etling State Park. 1 September 1974. E. Wilson. Verified by C.C. Carpenter. University of Oklahoma Museum of Zoology, UOMZ 34348. OKLAHOMA: Cimarron Co: 9.3 km N Kenton. 21 August 1976. K.L. Soltesz. Verified by H.M. Smith. UOMZ 34828. First voucher specimens from Cimarron County, and the Oklahoma panhandle. Previously reported from Cimarron County by Blair (1950, Copeia: 234) but no specimens were retained. Submitted by Kenneth L. Soltesz, Denver Zoological Gardens, Denver, Colorado 80205.

SISTRURUS MILIARIUS STRECKERI (Western pygmy rattlesnake). USA: MISSOURI: Douglas Co: 5 km N Vanzant. 25 November 1976. D. Bergerhouse. Verified by J.K. Tucker. Private collection of G.L. Paukstis. Extends range 47.2 km N and 70.4 km NW of nearest recorded localities (Anderson, 1965, Reptiles of Missouri, Univ. Missouri Press, Columbia). Submitted by Gary L. Paukstis, Department of Biological Sciences, Illinois State University, Normal, Illinois 61761.

News Notes

PISANI NEEDS DIRT

Herpetological Review co-editor George R. Pisani is preparing a special satirical issue to be distributed at the 1977 SSAR-HL-KHS annual meeting in Lawrence, Kansas. Persons interested in contributing material of an appropriately sacrilegious nature should have it reach George before 31 May 1977. All suitable material which can't be fit into this year's issue will be held in the hope that this publication will become a fearfully anticipated annual event. See the inside front cover for George's address.

GEORGIA HERPETOLOGICAL SOCIETY

The Georgia Herpetological Society (formerly the Southeastern Herpetological Society) has recently been organized. Membership in the GHS is open to anyone interested in amphibians and reptiles. Members receive the Journal of the Georgia Herpetological Society (4-5 issues per year). Membership is $8.00 per year, and should be remitted to: John C. Zegel, GHS, 5341 Smoke Rise Drive, Stone Mountain, Georgia 30087.

WANTED: HERPETOLOGICAL PAPERS FOR PUBLICATION

The Chicago Herpetological Society desires manuscripts on natural history, conservation, husbandry and other topics of herpetological interest. Papers written for herpetology, ecology, animal behavior or biogeography classes may be suitable for publication and of interest to the CHS membership. Material of a highly technical nature which would normally be published in a professional journal is discouraged. Requests for information and manuscripts should be sent to John Murphy, Publications Secretary, Chicago Herpetological Society, 2001 North Clark Street, Chicago, Illinois 60614.

BIOLOGY OF THE REPTILIA: VOLUME VII

Carl Gans advises that Volume VII of the Biology of the Reptilia is now in press and Volume VIII should go to the printers in October. The editors have prepared a complete listing of present and proposed chapters and volumes coupled with a questionnaire designed to elicit comments and suggestions from herpetologists and vertebrate biologists generally. A copy may be obtained by sending a stamped (15¢) self-addressed envelope to him, at: Division of Biological Sciences, University of Michigan, Ann Arbor, Michigan 48109.

NICARAGUAN AMPHIBIANS

Plans are underway for a second edition of Villa's "Anfibios de Nicaragua." A special effort will be made to revise and update the first edition. If you have comments, suggestions, unpublished records or information, or unusually good color photographs of Nicaraguan amphibians, please contact by foreign air mail, as soon as possible: Jaime Villa, Apartado Postal 427, Managua, Nicaragua.

ASIH AT GAINESVILLE, FLORIDA

The 57th annual meeting of the American Society of Ichthyologists and Herpetologists will be held on 19-25 June 1977 at the University of Florida, Gainesville. Individuals interested in attending this meeting or obtaining additional information should contact: Carter Gilbert, ASIH Local Chairman, Florida State Museum, University of Florida, Gainesville, Florida 32611.

CINCINNATI COLLECTION RETURNS TO MUSEUM

The preserved collection of amphibians and reptiles of the Cincinnati Museum of Natural History, accumulated by Dury, Weller, Maslowski and others during the 1930-1950 period, has been officially transferred from the University of Cincinnati (UC) to the Museum. UC obtained the collection from the CMNH in 1957 on a long term loan. This collection ranks with those at the University of Louisville and the University of Kansas in containing the largest and most important collections of amphibians and reptiles from Kentucky. Interested individuals may obtain more information about the collection by contacting: Dr. R.A. Davis, Cincinnati Museum of Natural History, 1720 Gilbert Avenue, Cincinnati, Ohio 45202.

TURTLE HOBBYIST NEWSLETTER AVAILABLE

A monthly newsletter directed to those that keep turtles and tortoises in captivity has recently been published. Titled, "Turtle Hobbyist," the newsletter is published by Christel Pfeiffer and Mary Trotter, 5163 East Bedford Drive, San Diego, California 92116. The publication is intended to assist hobbyists with the proper maintenance of turtles, and will suggest methods of housing, breeding, diet, and preventative health methods. The six to eight page newsletter is published monthly, and is $5.00 per year or 50¢ per issue for sample copies. For additional information, write to: Turtle Hobbyist, 5163 East Bedford Drive, San Diego, California 92116.

PRESSURE FROM PET TURTLE INDUSTRY

Last May the Food and Drug Administration, contending that pet turtles carry salmonella, banned their sale in the USA. But the $8-million industry, based in Louisiana, has not taken the ban lying down. The National Turtle Farmers and Shippers Association, Inc., represented by the state attorney general, filed suit to have the ban lifted. When the FDA challenged the state's right to sue on behalf of the industry, the U.S. District Court ruled the suit was valid. Now the original case is awaiting reassignment following the judge's untimely death.

Meanwhile the industry, chiefly with the aid of microbiologist Ronald J. Siebeling and a NOAA Sea Grant, is hard at work developing a method for producing salmonella-free turtles. According to an article by Sally Kuzenski in a recent issue of Sea Grant '70s, Seiberling in his research at Louisiana State University (LSU) has already found one technique that works. He took about 30,000 freshly laid turtle eggs and chilled them in an antibiotic solution, which was drawn into the eggs as the cooling progressed. The hatchlings remained germ-free for the eight months they spent in the laboratory.

Now Siebeling is working on what may be an even better method. The gases are removed from cleansed eggs that have been placed in a vacuum tank. Then the eggs are soaked in gentamicin (the FDA-approved antibiotic used in treating turkey eggs) and incubated in sterile containers instead of the soil-sawdust-peat moss mixture previously used. Since the farmers themselves have been applying the method--"The LSU labs have been used only for analysis," says Siebeling--they won't need to be convinced of its efficiency or effectiveness in producing salmonella-free turtles. Their hope, then, is that through the courts they can convince the government that the turtles are now safe and can be sold again as pets.

...from BioScience (27(1): 68.

FORT WORTH ZOO NEEDS RHINOBOTHRYUM

Since March of 1974, the Fort Worth Zoological Park has maintained a single adult female specimen of Rhinobothryum bovalli (Serpentes: Colubridae), supposedly from Costa Rica. As far as we know, this is the only living specimen of this species in the United States. We would very much like to obtain a male, and would appreciate hearing from anyone who presently has or has access to additional living specimens. Contact: Bern Tryon, Fort Worth Zoological Park, 2727 Zoological Park Drive, Fort Worth, Texas 76110.

PYTHON DATA NEEDED

The Institute for Herpetological Research is collecting data on mating and reproduction of pythons, for the purpose of maintaining a data bank. Pre-stamped data questionnaires will be sent at no charge to institutions or individuals who have had experience in python reproduction and wish to share this information. Address inquiries to Richard Ross, M.D., Director, Institute for Herpetological Research, P. O. Box 2227, Stanford, California 94305.

COSTA RICAN HERP PROJECT

The Departmento de Ciencias Forestalas, Centro Agronomico Tropical de Investigacion y Ensenanza (CATIE) in Turrialba, Costa Rica, needs assistance in a series of 14 studies that they wish to carry out in the CATIE area. One of the studies involves a survey of the amphibians and reptiles, and will result in the publication of an illustrated guide to the common herpetofauna of the CATIE area. CATIE is able to provide laboratory space and perhaps some limited field assistance with the study. No salary or stipend money is available. Because living and working facilities at CATIE are already established, it would be possible for investigators to immediately get to work without worrying about logistical problems in the field. Interested persons may obtain additional information about this project by contacting: Dr. Gerado Budowski, Jefe del Departamento de Ciencias Forestales, Centro Agronomico Tropical de Investigacion y Ensenanza, Turrialba, Costa Rica, Central America.

NEW YORK ZOO TORTOISE BREEDING

The trio (⅓) of Radiated tortoise pooled in a breeding program by the New York Zoological Society and Dr. William H. Zovickian has produced 9 hatchlings from 13 eggs in 1976. Two 6-egg clutches laid late in the season are still incubating.

The eggs were incubated at 29°C. in a chicken egg incubator and hatched in 90-106 days. Four hatchlings emerged from a 5-egg clutch laid by one female, and five hatchlings resulted from 8 eggs (two clutches) laid by the other female. The adult tortoises and hatchlings are maintained by Dr. Zovickian in Sharon, Connecticut.

A similar program for breeding Geochelone yniphora has been initiated, but additional specimens, especially mature females, are needed.

CHANGE IN ALLIGATOR STATUS

On January 10, 1977, the USDI Fish and Wildlife Service announced in the Federal Register (42 FR 2071-2077) the determination that the American alligator is reclassified to be a Threatened species in all of florida and certain coastal areas of South Carolina, Georgia, Louisiana, and Texas. The exact boundaries of the Threatened populations may be found on p. 2077 in 17.42(a)(2)(iv) of the Special Rules. Alligators in all other portions of the species' range remain Endangered, except in Vermilion, Cameron, and Calcasieu Parishes, Louisiana, and in captivity wherever found, where they have been previously determined to be Threatened by Similarity of Appearance only.

Particular attention is called to the other provisions of the Special Rules applicable to the Threatened alligators. These rules provide that duly authorized Federal or State employees or agents may, in the course of their official duties, take without a permit, Threatened alligators which are sick, injured or orphaned. Furthermore, a permit would not be needed to lethally take a Threatened alligator which constitutes a threat to human safety, provided that live-capturing or other means of handling the problem are not feasible. Such employees or agents may also dispose of or salvage dead specimens. Finally, the rules provide that in any State operating under a Cooperative Agreement with the Fish and Wildlife Service, designated employees or agents may take Threatened alligators in the course of scientific research or conservation programs, and the hides of alligators so taken may be sold by the State, after they have been properly tagged and recorded, to federally licensed buyers. In all other respects, Threatened alligators continue to receive the same protection provided to Endangered alligators by the Endangered Species Act of 1973.

ERRATA

Second generation reproduction and courtship behavior in the Trans-Pecos ratsnake, Elaphe subocularis. HR 7(4): 157, para 3, line 6, "19958)" should read (1958).

Notes on reproduction in captive Lampropeltis triangulum nelsoni (Serpentes: Colubridae). HR 7(4): 162, Literature Cited, delete the reference to Trapido, H. 1940, and change Tyron, B.W. 1975 from "Herp" to Bull. New York Herp. Soc.; Table 1 caption, change "date" to read data.

Current Literature

As of January, 1977, approximately 70 searchers are scanning 400 journals. Titles will be published four times per year. Searchers are encouraged to submit titles for inclusion at three month intervals to assure approximately equal listings in HR. CAECILIANS OF THE WORLD

A TAXONOMIC REVIEW

by Edward Harrison Taylor

The definitive, classic taxonomic reference by world-renowned herpetologist Edward Taylor, describing over 160 species and subspecies of Gymnophiona, least known of all ordinal groups of vertebrates with the exception of certain orders of deep-sea fish. Over 800 pages with more than 400 illustrations, keys, and tables. "An invaluable reference work." *American Scientist*

List $25.00 **Sale price $6.25**

Sale ends July 1, 1977. All orders must be postmarked by that date. All sales final. Payment must accompany order. Kansas residents add 3.5% sales tax.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of Herpetological Review in 1967 (Corson Hirschfeld, Editor):

> "Herpetological Review incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the Review will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Now in its tenth year, Herpetological Review remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the Journal of Herpetology -- see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Authors are urged to write the editors before submitting feature-length articles. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles are desired. Submissions should be black-and-white, 8 X 10, glossy prints, and should be accompanied by a descriptive caption and exposure data. The name and address of the contributor should be taped or penciled on the back of each print. Please DO NOT send photographs before corresponding with the editors about them. Return of unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions can be supplied if desired. Contributors will receive ordering information prior to publication of their material. Herpetological Review will accept commercial advertising. Rates and copy information are available from the editors.

Milwaukee, Wisconsin 53233

Dear Dr. Nickerson:

I hope that the SSAR will support the National Audubon Society's recommendation to relocate American alligators. The American alligator is an aquatic animal, and theoretically at least, the ecological barriers separating "coastal" alligators from "inland swamp" alligators are poorly defined. I believe that these barriers are non-existent in some situations.

The alligator has made a successful recovery in parts of it's range, however, it is still completely extirpated, or is much reduced in numbers, in other areas.

It will be necessary to "transplant" alligators to some of these areas, if we want to re-establish the species throughout it's former range (with the possible exception of Miami and New Orleans).

I do not think that the transport and release of "coastal" alligators to inland habitats will result in their cruel death.

The alligator is a very tenacious animal, and one is on record (Barton, 1955) as probably surviving for at least six years in an Allegheny County, Pennsylvania swamp. This animal was finally shot by a local peace officer. Please do not interpret this to mean that I am suggesting that alligators be released in Pennsylvania, I merely mention this to support my contention that alligators are very adaptable creatures. Habitat manipulation is not necessarily wrong. State and Federal Game Departments have long used such methods to restore depleted species.

Finally, the reintroduction of American alligators to suitable habitats within their natural range can hardly be equated to the introduction of exotic species.

Sincerely yours,

J. Kevin Bowler

J. Kevin Bowler
Curator of Reptiles

TO THE SOCIETY,

This issue of Herpetological Review ends my editorship and the total publication services provided to SSAR by the Milwaukee Public Museum. It is somewhat ironic that this is the first issue of Herpetological Review to be fully composed. We were fortunate to obtain a grant from the Walter and Olive Stiemke Foundation, of Milwaukee, for the purchase of a Compugraphic Compuwriter II TG (Figure 1). With this machine we can produce a more professional appearing copy, reduce the amount of time needed to produce photoready copy and increase the amount of copy per page.

Figure 1. Ms. Susan Pleskatcheck operating Compugraphic Compuwriter II.

The next issue will be produced under the co-editorship of Joseph T. Collins and George R. Pisani of the University of Kansas, Lawrence. Richard Worthington of the University of Texas-El Paso will assume the responsibility for the Current Literature. They have already begun the production of HR 8(1) and the Society is fortunate to have such capable individuals willing to donate their efforts.

Donated effort has been the trademark in the production of Herpetological Review at Milwaukee. I gratefully acknowledge the assistance and support of MPM administration and the HR Section Editors. On behalf of SSAR and HR I personally thank Susan Pleskatcheck, Robert Henderson, Richard Sadjak, Teresa Noeske, Stephen Yeo, Nathan Kraucunas, Milton Spearbraker, Vivian Muench, Jon Shapiro, Cheryl Castelli, Janice Mahlberg, Karen Slowiak, Barbara Villa, Sue Kraegel and the host of others who have made publication possible. It has been fun...anguish...and really quite an experience.

HAPPY HOLIDAYS,

MAN

EDITOR, H.R.

SECOND GENERATION REPRODUCTION AND COURTSHIP BEHAVIOR IN THE TRANS-PECOS RATSNAKE, *ELAPHE SUBOCULARIS*

Although captive breeding of the Trans-Pecos ratsnake, *Elaphe subocularis,* has been recorded (Campbell, 1972), there are no reports of captive bred second generations. The present report deals with successful second generation captive reproduction of this species in two consecutive years with notes on courtship, care and growth of the young.

An adult male *E. subocularis,* collected 19 June 1968 12 miles north of Shafter, Texas on Highway 167, and an adult female, collected 16 July 1968 10 miles north of Fort Davis, Texas on Highway 17, were presented to the Dallas Zoo. Although no copulation was observed, the female laid six eggs on 6 April 1973. On 21 July 1973, after a 105-day incubation period, five of the six eggs hatched. On 12 June 1974, a pair of these juveniles was presented to the Fort Worth Zoo.

The young *Elaphe subocularis* were housed together on exhibit in a 3 foot fiberglass cage (Hulsey, 1974), with pea gravel, several small rocks and plastic plants added for decoration and to act as retreats for the young snakes. Although no courtship was observed, on 8 May 1975 the pair was in active copulation. After a slight disturbance, the two snakes quickly separated and were not seen to copulate after this date. On 19 May the pair was weighed on a triple beam balance, and measured using the squeeze box technique (Quinn and Jones 1974). Total lengths and weights of adult and juvenile snakes are given in Table 1.

The female readily accepted food weekly after copulation, and although she was becoming noticably larger posteriorly, it was doubted that *E. subocularis* of this size and age could be gravid. However, on the morning of 11 June 1975, a clutch of three large non-adhering eggs was laid near the rear of the cage and water bowl, and the female was coiled partially about them. The eggs were immediately removed and no aggressive behavior was displayed by the female. The three eggs were soft, white in color and somewhat moist, indicating they had been laid no more than one hour before discovery. Egg diameter varied from 19 mm to 21 mm (mean 20.3 mm), egg length varied from 62 mm to 73 mm (mean 66.0 mm), and egg weight varied from 17.9 g to 18.9 g (mean 18.3g).

The eggs were placed but not completely covered in a medium of four oz. of vermiculite and four fl. oz. of water in well-sealed one gallon jars (Tryon, 1975). These were then placed in an incubator in which the temperature fluctuated between 28 and 32 C. At approximately two week intervals the jars were opened briefly to replenish the oxygen. On 12 August 1975, after 63 days, eggs 1 and 2 developed slight indentations, and on 15 August, an indentation developed on egg 3. At 1300 h, 21 August, one longitudinal slit appeared in egg 3 and at 0800 h, 22 August, several slits were noted in all three eggs. The young snakes remained inside the eggs approximately 24 hours before emerging. Incubation times were 73 days for eggs 1 and 2 and 74 days for egg 3. All three snakes shed for the first time on 1 September.

The hatchling snakes were housed in a 1 foot fiberglass cage (Hulsey, 1974), and substrate and cage props closely paralleled those of the parent snakes' enclosure. Feeding on newborn mice took place at weekly intervals. At approximately six months of age all three juveniles began accepting small, pre-killed furred mice, but only if fed immediately prior to this on a live, hairless mouse. At one year of age, all juveniles were feeding entirely on small, pre-killed mice. During the first eight months after hatching, the snakes were fed individually in gallon jars to assure that each could feed without competition. Weights and measurements were recorded at seven months and twelve months of age.

The parent *E. subocularis* remained together on exhibit without further observed sexual activity until 26 June 1976. Then both snakes were extremely excited and moving rapidly about the cage. The male was aggressively pursuing the female, and upon locating her, he would bite any exposed portion of her body. This activity continued throughout the day but no copulation was observed. Gillingham (1974) noted that male western fox snakes, *Elaphe v. vulpina,* exhibited biting behavior just prior to and during copulation. It was thought that biting enhanced the receptivity of the female as well as anchored the male in position during coitus. In all cases the female was grasped behind the head, but not until she had signalled her receptivity by stopping after an initial chase.

Present observations indicate that biting is also included in the courtship of *E. subocularis,* only in a more random sequence. During the eight-hour period of observation there seemed to be a continuous chase response. Biting occurred at any time contact was made regardless of the area of the female's body located. Bites were quick, occasionally with some chewing motions, and appeared quite hard. Several seconds after biting had been initiated, the female resumed her flight, the male released his grip, and the chase began once more. At no time during observation did the male attempt copulatory position. As in *E. v. vulpina* (Gillingham, 1974), it is thought that biting activity in *E. subocularis* is used as a further stimulus to initiate receptiveness in the female, and not as a restraining measure. Because further courtship activity was not noted after 26 June 1976, it was assumed that copulation occurred during that night. In 1975, biting behavior was not observed when copulation took place.

The adults were weighed and measured on 4 July 1976. On 13 July, a bowl filled with damp sphagnum moss was placed in the cage to provide a deposition site. The female began spending more time in the bowl until 31 July when she was discovered beneath the sphagnum coiled around a clutch of four non-adhering eggs. The eggs were identical in appearance to those described above.

Incubation procedure was the same. Egg diameter varied from 22.0 mm to 24.0 mm (mean 23.0 mm), egg length varied from 60.0 mm to 73.0 mm (mean 66.0 mm), and egg weight varied from 21.5 g to 23.6 g (mean 22.6 g).

On 4 October 1976, egg 3 appeared indented dorsally, and at 0800 h, 12 October, it was noted that egg 4 had been slit several times and the snake's head was exposed. Between 0900 h and 1300 h, eggs 1 and 3 slit and the snakes' heads were exposed. At 1500 h, hatchling 3 emerged after an incubation time of 74 days. At 1800 h, 13 October, hatchlings 1 and 4 were coiled outside the egg on the vermiculite, and egg 2 was slit. Incubation time was 75 days. Hatchling 2 emerged at 0800 h, 14 October. Incubation time was 76 days.

Fitch (1970) states that within the genus *Elaphe* there are notable differences in the lengths of time required from hatching to sexual maturity. These range from less than two years in species such as *E. quadrivirgata* and *E. guttata* (in captivity) to four years in *E. obsoleta.* Bechtel and Bechtel (19958) found that in both sexes of *E. guttata*, sexual maturity is attained in approximately 18 months, and that females raised in captivity consistently laid their first clutches at two years. It is apparent that *E. subocularis* is similar to *E. guttata* in this respect but, as suggested by Fitch (1970), perhaps their development was accelerated by the prolonged season of activity and feeding that captivity affords.

ACKNOWLEDGMENTS

I wish to thank the staff of the reptile department at the Fort Worth Zoo for making this paper possible, especially J.P.Jones for recording a portion of the data in my absence. I am also indebted to James B. Murphy of the Dallas Zoo for information regarding the original pair of *E. subocularis* donated by Luther Sims.

F.W. PUTNAM'S ORIGINAL DESCRIPTION (1862) OF A DOUBLE-HEADED, BISEXUAL BLACK RACER (*Coluber constrictor* LINN.) - A HISTORICAL RECORD.[1]

I. Introduction -- Brief biographical sketch of Putnam with special reference to herpetology.

Frederic Ward Putnam (1839-1915) was born at Salem, Mass., and as a boy studied natural history as a hobby. He published his first paper at the age of 16 on the birds of Essex County. The following year, he was appointed Curator of Ornithology for the Essex Institute, where he had for some time assisted Dr. Henry Wheatland, President and guiding light of the Essex Institute. When Louis Agassiz came to the Institute to see the collection of turtles, he was impressed by the young Putnam's knowledge of natural history in general, and turtles in particular. Subsequently, he became a student-assistant of Agassiz at the Lawrence Scientific School of Harvard University. In 1859, Putnam was made Curator of Ichthyology for the Museum of the Boston Society of Natural History. He also served on the Committee for Fishes and Reptiles. In 1864 he returned to Salem as Curator of Vertebrates and Director of the Museum for the Essex Institute. Three years later when George Peabody founded the Peabody Academy of Science, which acquired the scientific collections from the Essex Institute, Putnam was made Director of the new museum. While at the Academy, Putnam became one of the founders of the *American Naturalist* and of the American Society of Naturalists. In the summers of 1873-74, he taught at Louis Agassiz's summer school on Penikese Island. This was formally known as the Anderson School of Natural History, and was the first marine summer school in North America. Following that, Putnam was a member of the Kentucky Geological Survey, for which he studied especially cave vertebrates.

For two years, beginning in 1876, he was part-time Curator of Fishes at the Museum of Comparative Zoology. But from 1875, when he was appointed Director of the Peabody Museum of American Archaeology and Ethnology at Harvard University, he devoted most of the balance of his life to American Archaeology. However, he retained an interest in zoology, especially herpetology, over the remainder of his life (Dexter, 1966).

II. Original Description of Specimen.

In 1862, while a student of Louis Agassiz, Putnam wrote the following description (unpublished until now) and made sketches of a double-headed, bisexual black racer (*Coluber constrictor*) which had been received at the Museum of Comparative Zoology in 1849.

This specimen is still preserved in the herpetology collection and cataloged under Museum No. 20183 M.C.Z. The external genitalia are clearly visible and are illustrated in Putnam's sketch (Fig. 1), but the specimen has never been dissected. While there are other records of axial bifurcation in snakes, this one is unique in that it is bisexual as well as bicephalic. The specimen has been carefully examined by the writer who has made a study of Putnam's original notes and sketch. Putnam wrote,

> "This specimen was given to Professor Agassiz in 1849 by Mr. Wells--it was taken in some part of Massachusetts. It is evidently a young snake and probably not more than a few days from the egg. Its whole length is 8 and 8/10 inches, length of tail 2 and 2/10 inches, length of head 5/10 of an inch, width between eyes 2/10 of an inch, distance from tip of snout to the point of the two heads 7/10 of an inch.
>
> The specimen is perfect in every respect. The scales are all normal excepting a slight indication of division of the abdominal scutellae, by a faint line through the center from point of union of heads to tip of tail.
>
> There is a kind of hump, where the two heads unite about half an inch in height. Seventeen dorsal rows of scales round the neck of each head, round the hump and round the normal body. One hundred and seventy-four abdominal scutellae (with a tendency to divide); about 85 to 90 subcaudal scales.
>
> All young snakes just from, or in, the egg have the penis protruded and there are generally two penes--now in this specimen there is a penis protruded on the right side, while on the left side as far as can be seen without dissection is a female second opening. The umbellicus is not yet closed and is situated about one inch from the anal opening and occupies the space of three of the scutellae.
>
> The mouth and throat seem to be perfectly formed in both heads. The teeth are small, but well developed for a young snake. The color is the normal color of young black snakes--58 distinct dark blotches saddling the back from head to anus, from here to end of tail the dorsal portion is of a much darker brown color which also extends forwards upon the scales under the dorsal blotches to near the center of the body. On the sides and on the abdominal scutellae of the anterior 2/3 of the body are small, dark, grayish spots about the size of small pinheads--irregularly placed along the sides. The rest of the under-side is of a dirty white. The general color is of a dirty gray with the blotches darker."

III. Subsequent Studies.

Jeffries Wyman (1865) reported at a meeting of the Boston Society of Natural History, 21 January 1863, on two anomalous snake specimens. Included was the black racer (M.C.Z. 20183) described, but unpublished, by

Putnam the year before. The proceedings stated that "Prof. Wyman exhibited drawings of two specimens of monstrosity in serpents. One of these, presented to him by Professor Agassiz, was of a young black snake, (*Coluber constrictor*) which had two complete heads united to a single trunk. The vertebral column was double for the short distance behind the head, and over the same region the transverse black bands, usually found in the young of this species, were divided lengthwise." R.H. Johnson (1901) described 13 two-headed snakes and reviewed others previously published. He mentioned very briefly the specimen of black racer reported by Wyman as mentioned above and illustrated it with an x-ray photo, but did not describe it. He added nothing to Wyman's incomplete account and named the specimen *Bascanium constrictor* Linn. Five cases of cephalic bifurcation of this species were listed.

Bert Cunningham (1937) published a monograph on "Axial Bifurcation in Serpents" which was "A historical survey of serpent monsters having part of the axial skeleton duplicated." He showed that the oldest record goes back to Aristotle in the fourth century B.C. and provided a bibliography of 101 references to original descriptions of bicephalism published between 1545-1932. The total number of fully authenticated records numbers 170. More records were obtained from the United States than any other country. Cunningham suggests that bicephalism was "caused by a partial separation of the two blastomeres formed at the first cleavage or in telolecithal eggs by a partial splitting of the embryonic disc at some comparatively early stage." Unaware of Putnam's study, he illustrated the snake and wrote that "Wyman recorded a two-headed *Coluber constrictor* given him by Agassiz, but he neither described it in detail nor secured it, probably because a more interesting monster was reported in the same article [actually it was an oral report given at a meeting]." At a later time when the black racer described here was examined and x-ray photographed by Johnson (1901) under the name of *Bascanium constrictor* Linn., he wrote, "This specimen found its way to the Warren Museum of the Harvard Medical School and then to the Museum of Comparative Zoology of Cambridge, Mass., from which it was borrowed by me to make the dorsal view shown in Fig.51, Plate V, and the x-ray photograph shown in Fig. 52. The animal is 10 inches in length, and the left neck is slightly longer than the right and has more vertebrae." However, Putnam's unpublished description still remains the most complete one recorded for this specimen.

[1] This paper was read at meetings of the Ohio Academy of Science held at Marietta College 21 April 1972. My thanks go to the family of F.W. Putnam for the privilege of quoting from his personal papers.

NOTES ON REPRODUCTION IN CAPTIVE *LAMPROPELTIS TRIANGULUM NELSONI* (SERPENTES; COLUBRIDAE)

Information on reproduction in the polytypic species *Lampropeltis triangulum* is scant in the literature, and is mostly concerned with forms restricted to the United States. Conant (1951), and Wright and Wright (1957) reported on eggs and young of the nominate form *L. t. triangulum*; Palmer (1961) and Groves and Sachs (1973) reported on *L. t. elapsoides*, and Fitch and Fleet (1970) provided information on *L. t. syspila*. Werler (1951) mentioned eggs and young of *L. t. annulata*, a form that enters southern Texas from Mexico. Little reproductive data are available on the Mexican forms of *Lampropeltis triangulum*. The present paper gives details of successful reproduction in captive *L. t. nelsoni* for three consecutive years.

One male *L. t. nelsoni* (total length 994 mm, weight 346.8 g) received 28 August 1964 and one female (total length 840 mm, weight 163.2 g) received 16 January 1967, were placed on exhibit at the Fort Worth Zoological Park. An additional adult female (total length 834 mm, weight 164.3 g) was obtained 5 September 1973, and the trio was placed together in a two foot fiberglass cage (Hulsey, 1973) in early October 1973. Pea gravel was used as a substrate, and rocks and plastic plants were added for cage decoration and security for the snakes. Temperature fluctuated seasonally between approximately 23 and 32° C, and the relative humidity was consistently high due to cage position. Fluorescent lighting was provided about ten hours daily. Each snake fed weekly on one or two 20 g mice.

Reproductive data are given in Table 1. Although actual copulation was never observed, courtship and attempted copulation were noted on several occasions during the first two weeks in June of 1975 and 1976. It was thought that copulation occurred during the night.

Eggs were laid by the most recently received female in 1974 and 1975 and by both females in 1976. Several weeks before deposition, the snakes refused food and appeared noticeably gravid. In 1974 and 1975, damp sphagnum moss was placed in the exhibit and was used as an egg laying area. In 1976, both females were isolated individually and were provided a bowl filled with the above medium. Several days before laying, each snake coiled beneath the sphagnum and remained there until deposition had been completed. The eggs were soft, white, irregularly shaped, and moderately adherent. Length and diameter of the eggs were measured with a vernier caliper, and weighed on a triple beam balance soon after laying.

The eggs were incubated in groups of two or three in well-sealed one gallon glass jars on a medium of four or six oz. of vermiculite and an equal number of fl. oz. of water (Tryon, 1975), and maintained between 23° AND 30 ° C. Hatching occurred in approximately sixty days. After several longitudinal dorsal slits had been made, the snakes' heads protruded, and in one to twelve hours each hatchling emerged and dug under the vermiculite. Lengths were recorded within several hours after hatching using the squeeze box technique (Quinn and Jones, 1974) and weights measured on a triple beam balance.

Juvenile coloration was similar to that of the adults only much brighter, and the white bands possessed a greenish tint dorsally. Of the thirteen total juveniles, none had the same sequence of complete and broken bands, and therefore each could be easily identified.

Ecdysis occurred from seven to ten days after hatching, and all hatchlings were induced to feed shortly thereafter on new-born mice. Growth was fairly rapid. For two 1974 hatchlings retained, a male and a female, mean total length increased from 265 mm to 795 mm, and mean weight increased from 9.5 g to 138.0 g in approximately two years. Above measurements and weights for the adult snakes were taken 4 October 1976.

ACKNOWLEDGEMENTS

We wish to thank J. A. Campbell, Hugh Quinn, and the staff of the Fort Worth Zoological Park for their comments and assistance. We are most grateful to Joseph Laszlo for the loan of the female snake.

WEST MALAYSIAN TURTLES: UTILIZATION AND CONSERVATION

INTRODUCTION

Hanging appendix-like below the belly of Asia, the Malay peninsula extends as a long, narrow backbone of a mountain range that originates in Burma and Thailand. The southern third of this peninsula, reaching to within 2° of the equator, is the mainland portion of Malaysia, West Malaysia. In this lush, tropical land exists one of the world's most diverse asemblages of turtles. Some five families, twenty genera, and twenty-three species (Table I) have been reported for this area which is slightly smaller than the state of Illinois. As in other developing countries, there is a heavy demand for these species and their products. But unlike so many other countries in this region, the value of turtles as a renewable resource is recognized in West Malaysia and efforts are being made to conserve them for future generations.

This report describes the usage of turtles in West Malaysia and reviews laws and conservation measures currently being undertaken to protect these valuable species.

THE FAUNA

The batagurine emydids, largest and most varied chelonian group in West Malaysia, comprise 48% (11/23) of the species. The members range in size from *Cuora amboinensis* and *Siebenrockiella crassicollis* which seldom attain carapace lengths of 200 mm to *Orlitia borneensis* which may approach 800 mm carapace length. In habits a few are chiefly aquatic (e.g. *Batagur baska* and *Callagur borneoensis*) but most tend to be amphibious (e.g. *Notochelys platynota, Cyclemys dentata, Heosemys grandis*. *Heosemys spinosa* seems to be the most terrestrial of the group.

Of the three testudinids reported for Malaysia, only *Geochelone emys* is at all common. They are today most numerous in hill and mountainous areas, perhaps because of human predation and development in the lowlands.

Representatives of all five genera of sea turtles occur along the coasts of West Malaysia, but inly *Dermochelys coriacea, Chelonia mydas,* and *Lepidochelys olivacea* nest in numbers; most nesting beaches occur on the east coast and associated islands. The *Dermochelys* nesting population, possibly exceeded only by one in Guiana, is one of the world's largest.

Four genera and species of trionychids have been reported from Malaysia. Three of the four (*Trionyx cartilagineus, Pelochelys bibroni* and *Chitra indica*) approach or exceed 700 mm disc length. The fourth (*Dogania subplana*) seldom reaches 250 mm. *Trionyx cartilagineus* is by far the most common and occurs in rivers, swamps, ponds and ditches throughout the country.

USAGE

Uses of turtles in West Malaysia fall into three somewhat overlapping categories: food, religious and superstitious purposes, and novelties for the tourist trade.

Certainly the chief importance of turtles to Malaysians is as food, the usage varying considerably with race and religion. Malays, who comprise over fifty percent of the population in West Malaysia, are prohibited from eating turtle (reptile) meat by the Islam faith. They can, however, eat turtle eggs which are considered a great delicacy and are said to have aphrodisiacal properties. Eggs of five species (*Dermochelys coriacea, Chelonia mydas, Lepidochelys olivacea, Batagur baska* and *Callagur borneoensis*) are common in local markets during appropriate seasons (Fig. 1). Whereas chicken eggs sell for US 4-6 cents each, *Chelonia* and *Lepidochelys* eggs cost 8-10 cents each and *Dermochelys, Batagur* and *Callagur* eggs cost 12-16 cents each. Eggs are eaten raw, soaked in brine and then boiled, or mixed with pullet (glutinous) rice.

The second largest ethnic group (37%) and the largest consumer of turtle flesh in West Malaysia is the Chinese. They eat most of the local species (excluding sea turtles) prepared in a variety of dishes. Beyond their delectability, chelonians are reputed to possess certain medicinal value. It is believed that one's kidneys, strength and virility all benefit from a properly prepared turtle dish. A jelly prepared by boiling a carapace with vinegar is used to treat fevers, debility, and acute rheumatism (Burkill, 1966). Softshells, chiefly *Trionyx cartilagineus,* are particularly esteemed for food. One delicious method of preparation is soup made from the flesh and cartilaginous portion of the shell with a variety of herbs, including ginseng. Hardshell turtles are steamed with Chinese herbs. Eggs are often eaten with wild honey.

Where religion allows, Indians also eat turtle, but comprising a small minority in the country, their impact on turtle populations is presumably light. An elderly lady told me that turtle meat steamed with Indian herbs could cure piles.

Finally the aborigines or Orang Asli (indigenous peoples of Malaya) eat turtle and are amazingly adept at finding them. Aquatic species are probed for in the mud and sand when waters are low or are speared from a prau (dugout) in clear swamps and rivers. Preparation is without frills; the plastron is opened and the intestines are removed, cleaned, salted and then replaced. The turtle is placed among the coals of an open fire until done. Turtles are considered an especially good find because they come equipped with their own cooking pot.

Although eggs are sold in markets on both coasts, turtles are common only in the west coast markets where most of the Chinese have settled. The east coast is predominately Malay. In the market in Telok Anson, a medium-sized western town, the most common species sold are *Trionyx cartilagineus* and *Cuora amboinensis* with

Siebenrockiella crassicollis and *Pelochelys bibroni* showing up occasionally. Softshells bring the best prices with young (more tender) *Trionyx cartilagineus* selling for US 80 cents per kati (1 1/3 lbs.). *Curoa* sell for 60 to 80 cents each. In addition to the market, turtles are sold in the so-called Chinese "pet shops". Here they are purchased for food, medicine, or occasionally as pets. In one large establishment I recorded the following species: *Callagur borneoensis, Cuora amboinensis, Cyclemys dentata, Geochelone emys, Heosemys grandis, H. spinosa, Notochelys platynota, Orlitia borneensis, Pelochelys bibroni, Siebenrockiella crassicollis,* and *Trionyx cartilagineus.*

Other than food, turtles have a certain religious significance to Chinese Buddhists and a number of turtle temples are scattered throughout Malaysia. According to popular belief, one finding a turtle and delivering it to one of these temples has saved a life and will be rewarded with good fortune and long life. In some temples, turtles are given no care but in others, where they have become a tourist attraction, vegetable greens are sold for visitors to feed the turtles.

Two of the most attractive and striking turtle temples are the Kek Lok Si Temple in Penang (Fig. 2 & 3) and Sam Poh Thong Temple in Ipoh. The former sits high on a hill overlooking the city of George Town. The latter is built into a cliff and sheer rock walls surround the turtle pool and garden on all sides. Within both temples one can see *Batagur baska, Callagur borneoensis, Cuora amboinensis, Heosemys grandis, Orlitia borneensis, Siebenrockiella crassicollis,* and even *Pseudemys scripta elegans* (a common US turtle sold in Malaysian pet shops). Several *Geochelone emys* were observed around the edge of the pool at Penang. *Heosemys grandis* was most common in both temples.

Easily the largest tourist activity related to chelonians is "turtle watching" which has created a sizeable industry on the east coast in recent years. During the sea turtle nesting season (May to September) thousands of tourists converge on the various nesting beaches, a practice being increasingly promoted in travel brochures. A number of motels cater to the "turtle watchers" and local entrepreneurs profit by selling food, drink, and protection for parked cars. Further it is not unusual to be walking down a seemingly deserted stretch of beach only to have someone dart out of the shadows to sell "turtle watching" tickets.

The most popular turtle watching area is a half mile stretch of beach at Rantau Abang, Trengganu, where the Department of Fisheries operates a hatchery and nesting sanctuary for the giant leatherback, *Dermochelys coriacea.* Here a series of small open coffee shops have been constructed where tourists can await the turtles which often do not emerge until 2:00 or 3:00 a.m. Unfortunately, these shops have greatly proliferated recently and their lights are becoming a problem, discouraging the shy leatherbacks from using the government's beach. Crowds are also becoming a problem; it is not unusual for a leatherback to lay its eggs while encircled by several hundred observers. One night in 1975 an estimated 4000 observers swarmed the nesting beach. Emerging turtles could find no open sand and eventually returned to water.

Fortunately, turtles have not become a big tourist souvenir item. Only *Eretmochelys imbricata* has joined the gaudy, stuffed, shellacked false gharials, crocodiles, monitor lizards, and cobra-mongoose displays in tourist shops of Singapore and Kuala Lumpur. Some tortoise shell (*Eretmochelys*) is also sold in various forms of jewelry. For the most part these hawksbill products come from Indonesia rather than local sources. I have seen no evidence that the reptile leather business is using turtle hides. Crocodilians, monitor lizards, and pythons are most commonly sold for this purpose.

LEGISLATION AND CONSERVATION

Malaysia is a conservation leader in SE Asia. This circumstance is partly because of the country's relatively high standard of living, partly due to enlightened leadership in those government agencies responsible for the nation's resources, and partly to a small but active band of conservationists. Spearheading many conservation efforts is the Malayan Nature Society, presently approaching one thousand members. The Society publishes THE MALAY NATURE JOURNAL for scientific publication and THE MALAYAN NATURALIST, a quarterly newsletter which covers recent conservation events and serves as a forum for members' conservation ideas. Beyond this the Society operates a speakers' bureau for schools and organizations, holds essay and art contests on conservation subjects, and generally publicizes conservation throughout the country.

Among its recent activities are several turtle-related projects. The Society is working with the Tourist Development Corporation to insure that increased tourist visitation and facilities at leathery turtle nesting beaches cause minimal disturbance to the turtles. On the west coast the Society is working to establish sanctuaries for *Chelonia mydas* and *Lepidochelys olivacea* on the tourist islands of Pangkor and Penang and a sanctuary for *Eretmochelkys imbricata* in the state of Malacca.

Two government agencies divide responsibility for turtles. Fresh water and terrestrial species fall under Game Department jurisdiction whereas salt water species are under control of the Department of Fisheries. These agencies enforce existing laws and set up government sponsored conservation programs.

Unfortunately, protection of declining species is hampered by a scarcity of existing laws. Only two of eleven states presently have laws controlling exploitation of inland turtles. In the state of Perak, two laws passed in

1915 offer protection to the genera *Orlitia, Batagur, Callagur,* and *Hardella.* Interestingly, the latter does not occur in Malaysia. Basic provisions of the laws prohibit certain types of traps in the nesting area at times when hatchlings are emerging, prohibit the killing of these genera on the lower Perak River, and give the state authority to license and lease egg-collecting areas. In 1972 the state of Kedah passed a similar law for licensing and leasing *Batagur* egg-collecting areas.

Four out of eleven states (Perak, Kelantan, Trengganu, and Pahang) have laws applying to sea turtles but the major emphasis is on licensing and leasing egg-collecting areas. Adults are given protection but egg-collecting is not restricted and thus almost all eggs laid are collected and sold.

To gain uniformity in turtle legislation throughout West Malaysia, a new law has been written that applies to *Batagur baska, Dermochelys coriacea, Chelonia mydas, Lepidochelys olivacea* and *Eretmochelys imbricata.* The new legislation transfers the authority and responsibility for turtle protection from the state to the Department of Fisheries (federal), providing more power and wider coverage over turtle management. Specific tenets of the bill provide for regulation of egg collection, killing and possession of turtles, tourist "turtle watching", cruelty to turtles, conservation programs and collection of statistics on nesting. The greatest obstacle in passing such sweeping legislation is that wildlife exploitation is the prerogative of each state and no federal law can be passed controlling this resource. Therefore each state assembly must pass the law separately for it to be accepted countrywide and whether all states will approve this new law remains to be seen.

Despite the inadequacy of existing laws, both Game and Fisheries Departments have begun active conservation efforts for endangered species. The Game Department in 1967, under the leadership of the present Chief Game Warden, Mohamed Khan, an avid conservationist and current president of the Malayan Nature Society, established a hatchery program for *Batagur baska* on the Perak River. Eggs are purchased from local licensed collectors and hatched in sand on an artificial beach. Hatchlings are then raised in captivity for one year and released on the natural nesting beaches. To date 6,000 to 7,000 *Batagur* have been returned to the Perak River as part of this program. The program is an important step in halting the decline of *Batagur* populations but a number of programs remain to be worked out. Low hatching success and the advisability of raising hatchlings in captivity are two problems under current study. Next year the *Batagur* program will be expanded with the establishment of a hatchery on the east coast's Trengganu River.

The Department of Fisheries currently operates a hatchery for *Dermochelys coriacea* in the state of Trengganu. The history of this project has recently been reviewed (Kiew, 1975). Briefly, the program was initiated by the Department of Fisheries and the Malayan Nature Society under the advisement of Dr. J.R. Hendrickson in 1961. The state of Trengganu financed the original project which produced 3,699 hatchlings from 8,366 eggs. With additional financial aid from the World Wildlife Fund, Fauna Preservation Society, and the Malaysian Government, the number of hatchlings released has grown steadily to 42,616 from 91,147 eggs in 1974. From 1961-1974, 244,392 hatchlings have been released. The present goal is to obtain 15% (ca. 180,000) of all eggs laid each year for the hatchery.

The Director of the Fisheries Department in Trengganu, Siow Kuan Tow, presently oversees the *Dermochelys* program. An active, imaginative biologist and administrator, Mr. Siow has grandiose plans for the sea turtle hatchery on Malaysia's east coast. Examples of future improvements that Mr. Siow would like to add to the program include: 1) fencing off five of the twelve miles of the *Dermochelys* nesting beach as a turtle sanctuary; 2) beginning similar hatchery programs for *Chelonia mydas* and *Lepidochelys olivacea*; and 3) establishing a green turtle ranch in a fenced-off natural pasture.

CONCLUSION

The future for chelonians in Malaysia looks brighter than in other parts of SE Asia, but there are still many problems which need attention. Considering the large numbers of turtles sold in markets and exported to Singapore for consumption each year, certain populations must be rapidly dwindling. Population studies are sorely needed to provide the base-line data necessary to assess which species are being over-exploited. At present those species nesting in mass on specific areas (i.e., *Batagur, Callagur,* sea turtles) seem most threatened, although the great demand for softshell meat requires that these species be watched closely as well.

Hopefully Malaysia's excellent beginning in turtle conservation will be continued and expanded to set an example for other nations in the area.

ACKNOWLEDGMENTS

I am indebted to Dr. Kiew Bong Heang, University of Malaya, Dr. Ronald Altig, Mississippi State University, and Mr. Siow Kuan Tow, Director of Fisheries, Trengganu, Malaysia for reading the manuscript and for offering various suggestions. The Game Department of West Malaysia has been very generous with assistance and equipment during my stay in Malaysia. Aspects of my research in Malaysia have been financed by grants from the World Wildlife Fund, the New York Zoological Society, Fauna Preservation Society, the American Philosophical Society, Illinois Academy of Science and Eastern Illinois University.

WORM SMAKES IN THE DIET OF A TOAD, *BUFO MELANOSTICTUS*

Campbell and Davis (Herpetologica, 1968, 24(4):327-328) summarized the literature dealing with stomach contents of field collected toads of the genus *Bufo*. They also reported the first vertebrates in the diet of any member of the genus *Bufo*; *Sceloporus undulatus* and a juvenile *Bufo woodhousei* having been ingested by *Bufo valliceps*.

On 15 June 1975 while in Lundu, 1st Division, Sarawak, Malaysia, I collected 10 adult *Bufo melanostictus*, one of which disgorged a dead *Typhlina bramina* while being preserved. Later dissection of the other 9 preserved toads revealed 3 additional *T. bramina* in the stomach contents. None of the worm snakes showed much damage as a result of being ingested.

Checking the stomachs of the relatively easily collected, larger species of toads may prove to be a valuable source of much scarcer species of sympatric worm snakes.

GRANTS AVAILABLE FROM THE SAVANNAH RIVER ECOLOGY LABORATORY

The Savannah River Ecology Laboratory (SREL) of the University of Georgia is making available grants to eligible faculty and post-doctoral investigators (monthly salary up to $1,200 plus an additional $75/month when accompanied by dependents), for eligible graduate students (annual stipends of $3,000-3,600, plus tuition and fees and limited travel allowance) and, during the summer, eligible undergraduates (stipends of $90/week). Research areas of SREL resident faculty include bioenergetics, behavioral ecology, physiological ecology, population dynamics, community ecology, and herpetology.

For application materials and additional information, write to: Dr. Rebecca R. Sharitz, Faculty (Graduate, Undergraduate) Research Program, Savannah River Ecology Laboratory, Drawer E, Aiken, South Carolina 29801. The deadline for the receipt of all application material for the summer program is January 10, 1977. Appointments are announced in April.

AN UNUSUAL BASISPHENOID IN ONE SPECIMEN OF *GRAPTEMYS FLAVIMACULATA*

Skeletons of 18 specimens of *Graptemys flavimaculata* (TU# 15124, 15128, 15132, 15374, 15377, 15405, 15735, 15737, 15738, 15747, 15748, 15761, 15784, 15786, 15787, 15789, 15790, and 15791), collected from the Pascagoula River, Mississippi, and deposited in the Tulane University Museum of Natural History, were analyzed using a Bausch and Lomb dissecting microscope. From a palatal view, the basisphenoids of 17 of these specimens were observed to be unpaired, triangular elements, which project anteromedially between the pterygoids along three-fourths of their length. The base of this triangular element is oriented posteriorly, where it abuts the basioccipital by a crescent-shaped suture. Thus, the basisphenoid of these specimens is similar to that of most fossil and recent turtles. However, in one specimen (TU 15132), the basisphenoid was split into a distinct anterior and posterior portion, of approximately equal length, by a transversely oriented crescent-shaped suture. The division between these elements is not the result of injury to this bone, but apparently represents a normal sutural contact between two elements (Fig. 1).

Kunkel (1912) and Shaner (1926) reported that the basisphenoid of *Emys* and *Chrysemys* arises from two centers. The cartilage bone basisphenoid proper then fuses with the membrane bone parasphenoid, which lies anterior to the basisphenoid and beneath the hypophysis, during development. Thus, the "basisphenoid", found in this one specimen of *Graptemys flavimaculata*, probably represents a lack of fusion of these two elements during the development of this specimen. The anterior portion of this element would represent the parasphenoid of other reptiles, and the posterior portion would represent the basisphenoid proper, a condition previously unreported for turtles.

The presence of an unfused basisphenoid-parasphenoid is interesting for several reasons. First, the skeleton, which is often useful for taxonomic purposes, is generally considered to be relatively conservative, with respect to variability, as compared to various features of the soft anatomy. This is especially true for turtles which have remained relatively unchanged for millions of years (Romer, 1956). Variations in size, shape, or topography of various elements are relatively common in comparison to those involving addition, deletion, or incomplete development of skeletal elements, since most of the latter types of variability are often deleterious. Thus, the occurrence of an unfused basisphenoid-parasphenoid represents an abnormal variation in a normally conservative taxonomic character. This is especially significant in the case of *Graptemys flavimaculata* since the morphology of the basisphenoid has been found to vary interspecifically between *Graptemys flavimaculata* and *Graptemys nigrinoda* (Killebrew, 1976).

Secondly, the occurrence of an unfused basisphenoid-parasphenoid is significant from a developmental standpoint. Fusion of these elements during development is undoubtedly a genetically controlled phenomenon. Thus, lack of fusion of these elements must represent either an alteration of genetic information or a breakdown of normal developmental processes, without consequent deleterious effects on the animal.

The occurrence of an unfused basisphenoid-parasphenoid is also significant from the standpoint of the phylogenetic history of the group. In most primitive reptiles, including the supposed ancestors of the turtles, the cotylosaurs, a distinct parasphenoid and basisphenoid are present. However, these elements are fused in even the most primitive turtles that are now known to have existed (Romer, 1956). Thus, it is interesting that a character, not known to occur in any fossil or recent turtle, but one which was present in the ancestors of turtles, should appear in a present-day individual because of some genetic or developmental abnormality.

I thank Dr. Harold Dundee, Department of Biology, Tulane University, for providing the specimens used in this study. I also thank Dr. J. Martin Walker for his critical evaluation of this manuscript.

SKELETAL PREPARATION OF HERPETOLOGICAL SPECIMENS

The preparation of skeletons of small animals is of importance in a variety of disciplines. For fundamental taxonomic work it is essential to have perfectly clean preparations in which all small bones and delicate bone spurs and processes as well as cartilaginous connections remain intact. For studies on the morphologic basis of behavior (e.g. locomotion) it may be important to preserve the articulated integrity of appendicular elements such as the shoulder or pelvic girdles. In preparations destined for museum display or other artistic purposes, the physical appearance of the skeletal material may be of paramount interest. During our work at the Museum of Comparative Zoology, Harvard University, we have employed a method of preparation which achieves satisfactory results in each of these areas.

MATERIALS

1) Specimens - animals preserved in alcohol work best, but freshly killed specimens can also be used.

2) Clorox (5.25% sodium hypochlorite) - a strong acid or base can be used, but Clorox is most easily obtained.

3) Ethyl alcohol, 75% - acts as a weak base to neutralize the acidic Clorox.

4) Dissection instruments - forceps, scalpel and razor blades are the most useful. A fine and a coarse pair of forceps are necessary, and the scalpel must be sharp.

5) Anatomy book, reference skeleton, or other guide, for anticipating the structures to be encountered while dissecting.

METHOD

Preparing the specimen. The sex, relevant lengths, scale counts and other important character states should be recorded if needed. Slit the skin on the ventral surface of the limbs and in the throat region, and then peel off the skin from the entire body using forceps. Do not slit the skin on the chest as this may injure the cartilaginous structures of the sternum. The skin around the mouth can be slit at the gumline to facilitate removal of the head skin in one piece. The latter procedure allows retention of the scale characters of taxonomic importance. The empty skin should be tagged and retained. The skin of the head remains attached to the body if only a skull will be prepared.

When the skin has been removed use the scalpel and forceps to carefully cut and eliminate muscle and connective tissue from the bones and joints. Spare all cartilage, but remove soft tissue organs. Removal of the eyes is most easily accomplished by a snip with fine scissors. Remove the brain if possible by entering the foramen magnum with a fine hook or through the orbits with fine forceps. Be careful not to scrape the skull roof or any bones. Retain the hyobranchial skeleton, either dry or in alcohol. Note the presence of calcified endolymphatics. These structures should be kept intact, although the precise arrangement is up to the discretion of the researcher: skull (lower jaw may or may not be disarticulated); shoulder girdle; pelvic girdle; vertebral column.

The Clorox treatment. Place the animal in Clorox and observe it *closely*. This step is critical in that if the bones sit too long in the Clorox they will eventually become powdery and fall apart when dry. Cartilage is a good indicator for determining when the skeleton has been in the Clorox for the proper amount of time. When the cartilage starts to disintegrate (usually in 1-4 min) the skeleton must be removed and immediately placed in 75% ethyl alcohol. If the cartilage is allowed to completely disintegrate the bones will have become too deeply penetrated by the Clorox, and the alcohol immersion will not neutralize all the Clorox. This will cause the skeleton to progressively disintegrate over the coming months and years. The immersion times in Clorox and alcohol are size determined, with larger specimens requiring more time. If no cartilage is present as an indicator in the piece being skeletonized, a time limit of 2 min (or less) should be placed on the Clorox treatment. It may be necessary to follow the progress of some small structures under a dissecting microscope.

After the immersion in alcohol (3-5 min) continue by picking off the muscle and other connective tissues remaining on the bones. Sometimes repeated immersions in Clorox may be necessary to achieve a clean skeleton. These reimmersions should not exceed 1 min in length per reimmersion. A moistened cloth, medicine dropper or syringe full of Clorox may be used for problem spots in cases where total reimmersion is not desired. When the skeleton is adequately cleaned, let it sit in alcohol for 15-20 min, then let it dry. When skeletonizing a large amount of material it will be necessary to replace both the Clorox and alcohol when they lose their effectiveness. The Clorox can be seen to be ineffective when a new bone placed in it fails to become covered by small fizzling bubbles. The alcohol need not be changed as often as the Clorox.

Special considerations for frogs. When preparing a frog skull it is best to leave the anterior palate tissue attached and to not disarticulate the lower jaw. Frog digits should be left in the skin. Do not disarticulate the limbs at the wrist or ankle, unless one set of limbs is disarticulated and not the other.

Special considerations for turtles. Turtles may be prepared by leaving the shell whole, or by sawing across both bone bridges of the plastron. The whole shell may be prettier, but it will be much harder to work with. When sawing off the plastron, some shell is lost so that the two pieces cannot be fitted together exactly. Turtles of the suborder

Pleurodira (side-neck turtles) have the pelvic girdle connected to both carapace and plastron, so that when removing the plastron, the girdle element may be broken accidentally.

Working with a scalpel around the forelimbs and head region, the skin can be detached from the shell where they meet. Next the two front legs are removed taking care to detach all girdle elements. The neck is then snapped off to the eighth cervical vertebra. The same procedure can be used at the hind end, but it is all made easier if the plastron has been removed. If only the skull is wanted, the skin should be removed in such a manner that it remains attached to the body. This is best achieved by making two lateral incisions along the neck to the angles of the mouth and then freeing the two resulting flaps in the mid-neck region and working forward to free them from the skull itself.

Do not soak the outside of the carapace in Clorox; however, the inside of the carapace can be cleaned by pouring Clorox into it like a bowl. In case removal of the scutes is desired, they will either peel off easily, or in most cases come off with a chisel.

STORAGE

The completed skeletons are labeled and stored in cardboard boxes or in transparent plastic boxes. The latter allow the skeleton and its inside label to be clearly viewed without opening the box. Large pieces such as turtle shells may be put into plastic bags.

MISCELLANEOUS

Do not leave anything in Clorox for more than 10-15 min, for the results will be disastrous. Count on one half to one hour for the skeletonizing procedure, or much longer for medium to large-sized specimens. Gloves are cumbersome unless they are tight-fitting surgical gloves.

Skeletonization by dermestid beetles is a preferred method for unpreserved specimens, especially if only larger bones are involved. Preserved material may not be eaten by dermestid beetles and the Clorox method works extremely well. If an alcoholic specimen has dried out, it can be skeletonized, but it must be soaked in alcohol for a few days beforehand.

The main potential problem with the Clorox procedure is that if the Clorox immersion is too long then the skeleton becomes powdery and falls apart after some time. Using the method outlined above avoids that problem, and skeletons we have prepared are still in a perfect state after nearly five years.

COLOR PRESERVATION IN SALAMANDERS

Formalin fixation and alcohol storage have been the routine methods of choice for the preservation of amphibians and reptiles for museum collections. Although this method preserves vertebrate specimens very well over a period of many years, it has the disadvantage of bleaching some colors and darkening others, making identification of the organisms more difficult.

Several methods for the preservation of color in whole vertebrate specimens have been proposed. The use of ammonium sulfate (Windsor, 1971) and ascorbic acid with Prague powder [1] (Humason, 1967:515) as the active ingredients have been recommended, but the colors ultimately fade unless the specimens are kept in the dark. Noticeable fading occurs within the first month if they are exposed to light.

I have found that a paraformaldehyde-glutaraldehyde mixture at a pH of 7.0 to 7.1 will preserve the colors of the salamanders even though after fixation, they have been exposed to light (Sylvania "Lifeline"® fluorescent lights) for an average of 12 hours per day for eleven months.

Proposed Method. The fixative formula is basically that of Karnovsky (1965) for the preservation of tissues for electron microscopy, but modified to avoid shrinkage of the specimens.

Forty grams of paraformaldehyde powder are dissolved with constant stirring in 500 ml of distilled water at 65° C. The solution is then cleared with a few drops of 1 N NaOHwith constant stirring (the solution need not clear completely). Then add 100 ml of 50% glutaraldehyde and bring the volume up to 1000 ml with a sodium phosphate buffer (Hyat, 1970:342) adjusted to a pH of 7.1 to 7.2. The final pH should be 7.0 to 7.1.

This should be kept as a stock solution in a refrigerator for no more than a week because in solution the glutaraldehyde tends to polymerize. To use, the stock solution must be diluted to 60% by volume with distilled water. Whole specimens should be fixed for 24 to 48 hours (although one week will do no harm and it is especially recommended for reptiles). Inject all specimens with the solution to insure more even penetration of the glutaraldehyde. After fixation the specimens should be rinsed in running tap water for an hour and postfixed and stored in 60% ethanol (for reptiles use 70-75% ethanol).

Specimens of *Pseudotriton ruber, Hemidactylium scutatum, Plethodon glutinosus, Plethodon cinereus,* and *Notophthalmus viridescens* were preserved in our laboratory using the above method under the light conditions stated above and in eleven months have not shown any appreciable color loss.

Although all fixatives are toxic, special care must be given when handling the paraformaldehyde powder and the glutaraldehyde. The powder must not get into the air or irritation of the eyes and mucosal linings will occur; neither glutaraldehyde nor paraformaldehyde should come into contact with the skin. After rinsing in tap water and storage in alcohol the specimens are as handleable and pliable as those done by routine formalin fixation. Because glutaraldehyde will always leave trace amounts that cannot be washed away, a set of mixing and storing vessels should be used for this fixation method exclusively.

LATE SEASON HATCHING SUCCESS OF *ELAPHE O. OBSOLETA*

A clutch of 27 black rat snake eggs was discovered on 20 October 1974, near Valley Park, St. Louis Co., Mo., U.S.A. The eggs were within the interior of a fallen log measuring 1.8 m in length by 0.45 m in diameter. The outer zone (5 cm thick) of the log was a shell of hard wood and the eggs were located within the inner zone which was composed of rotted wood. The nest site was in an oak forest, 5 m from the edge, on a northern hillside.

Two young snakes were hatching when the nest was first discovered. One completed hatching and escaped. The eggs were then recovered nd revisited 25 October. Present were two empty eggs, two partially hatched but inactive young and 23 unhatched eggs. Four of the latter measured: 4.5 x 3.6 cm; 4.9 x 3.4 cm; 4.1 x 3.3 cm and 4.7 x 3.6 cm. The hatching young and two eggs were returned to the laboratory and kept at 27° C to see if they were still alive. After eight days all four were determined dead. All eggs contained well developed snakes; one measured 26.5 cm SVL.

Minimal air temperatures recorded between 15 - 24 October at nearby Webster Groves, Mo. ranged from 0-10° C. Freezing was recorded only on 21 October. Evidently, low temperatures killed most snakes before they hatched.

The data of hatching of this clutch appear to be the latest noted in the literature. Wright & Wright (1957) recorded hatching dates from late August until 2 October. Fitch (1963) found a group of recently hatched young in Kansas in the second week of October.

BUFO DAPSILIS MYERS AND CARVALHO, SECOND KNOWN SPECIMEN AND NEW TO PERU.

Bufo dapsilis was described by Myers and Carvalho (1945) on the basis of a single adult female from Bom Jardim, near Benjamin Constant, mouth of Rio Javary, Amazonas, Brasil. During the course of an investigation on the ecology of the reptilian fauna of the Upper Amazon, Iquitos Region, Peru (Dixon and Soini, 1975) one specimen of *B. dapsilis* (fig. 1) was found by Pekka Soini in the forest floor leaf litter near the village of Centro Union, near the east bank of the Amazon, Loreto, Peru, on 16-30 December 1972. This specimen (TCWC 42509) is a female with eggs and, though smaller than the holotype, is very similar to the latter. However, there are some minor differences. Myers and Carvalho (1945:14) state that the skin covering the cranium is loose and not ossified to the head and the bony ridges making up the cranial crests are soft, fleshy and not composed of bone. My specimen has the skin ossified to the skull and the cranial ridges are composed of bone. It would be highly unusual for any species of *Bufo* to have non-bony crests. I suggest that the cranium of the holotype may have been in a state of decalcification and, seemingly, without bony crests.

The color markings, condition of dorsal tubercles, shape of body, limbs and feet, size and condition of paratoid and associated body ridges of my specimen are very similar to those described for the holotype. A comparison of pertinent measurements are given in Table 1.

Table 1. Measurements of holotype of *B. dapsilis* (from original description) compared to those of TCWC 42509 (in mm.).

	Holotype	TCWC 42509
Snout-vent length	77	57.0
Head width	27	19.0
Head length	21	21.4
Head width at eyes	11	8.2
Hind limb length (anus to knee)	32	28.7
Hind limb length (knee to heel)	31	28.0
Foot length (heel to toe tip)	43	36.6
Eye diameter	8	6.0
Eye-nostril distance	6	5.0
Interorbital width	11	7.4
Internarial width	4	2.0
Vertical diameter of tympanum	5	4.7
Mandible length (rictus to symphysis)	20	15.4

LEPIDODACTYLUS LUGUBRIS (REPTILIA: GEKKONIDAE): A RECENT ADDITION TO THE HERPETOFAUNA OF NICARAGUA

Lepidodactylus lugubris Dumeril and Bibron, is a common house gecko of the western Pacific east to Hawaii; it has also been recorded in the Neotropical region from the mainland in Panama (Smith and Grant, 1961), Colombia, Ecuador and Brazil (Peters and Donoso-Barros, 1970).

On 13-14 February 1976 two of us (RWH, JV) observed and collected *L. lugubris* at night in the open corridors of a hotel in Bluefields, Depto. Zelaya, Nicaragua and observed it on other buildings in the town. The lizards were active on the walls in the dimly lit corridors. They tended to stay close to the ceiling and would usually dash into spaces between the wall and ceiling to escape. The collected specimens are now in the herpetological collection of the Milwaukee Public Museum (MPM 12641-43) and Villa's private collection.

On 15-19 February 1976 we observed and collected *L. lugubris* on Great Corn Island, Depto. Zelaya, Nicaragua (65 km off the Caribbean coast of southeastern Nicaragua). The geckos were observed at night catching insects on the outside wall of a building near a shrimp packing plant. Several of the lizards were collected and are in Villa's private collection.

Lepidodactylus lugubris is common throughout much of its range. Smith and Grant (1961) suggested that their specimen from the Canal Zone arrived from Hawaii and mentioned the species' "known stowaway proclivities." Our records are the first from Caribbean Central America and it is plausible the species arrived in Nicaragua aboard a ship that passed through the Panama Canal. As boats pass daily between Bluefields and Great Corn Island, the presence of *L. lugubris* at both localities is not unexpected.

At Bluefields *L. lugubris* was abundant in several edificarian situations and at Great Corn Island only one very localized population was observed; thus it seems probable that Bluefields was colonized before Corn Island. In 1966 and 1969 one of us (JV), on visits to both localities, did not find it. This would suggest that *L. lugubris* is a rather recent colonizer of Caribbean Nicaragua.

ACKNOWLEDGMENTS. - We thank H. Marx of the Field Museum of Natural History for the loan of comparative material and H.S. Fitch for comments on the manuscript. The first author thanks the Banco Central of Nicaragua for support of his field work.

THE THEODORE ROOSEVELT MEMORIAL FUND

The Theodore Roosevelt Memorial Fund provides financial assistance to individuals (especially graduate students and persons with recent graduate degrees) conducting research in North America in any phase of wildlife conservation or natural history related to the activities of the American Museum of Natural History. Grants are usually kept to small sums of not more than several hundred dollars. Most awards support field work, and funds are not made available for salaries or for the purchase of non-expendable equipment. Address requests for application forms and all correspondence to:

Theodore Roosevelt Memorial Fund
The American Museum of Natural History
Central Park West at 79th St.
New York, New York 10024

Deadline for application is 15 February.

The Environmental Biology Program at Southern Methodist University announces summer field courses at Taos, New Mexico 13 June - 15 July and 18 July - 19 August, 1977. Courses will include Herpetology, Mammalogy, Ecology (general), Genetics and Evolutionary Biology, Community Ecology, Aquatic Ecology, Plant Ecology, Field Botany, and Plant Kingdom. For information, write to Kirkland L. Jones, Department of Biology, Southern Methodist University, Dallas, Texas 75275.

HERPETOLOGISTS, AMPHIBIANS, AND REPTILES AND THE ENDANGERED SPECIES ACT OF 1973

Within the last few years, there has been increasing interest among herpetologists in the conservation of potentially endangered and threatened amphibians and reptiles. With the publication of "Endangered and Threatened Amphibians and Reptiles in the United States" by the Society for the Study of Amphibians and Reptiles, herpetologists can now responsibly judge the merits of proposed research projects and specimen collecting trips in light of the status of any state's herpetofauna as judged by those most familiar with it. On the national level, the Office of Endangered Species, U.S. Fish and Wildlife Service, under the mandate given by the Endangered Species Act of 1973, has compiled a list of Endangered and Threatened wildlife and plants. the purpose of this law is to not only identify native and foreign wildlife and plants that qualify under its provisions, but also to provide protection to the organisms and ecosystems on which they depend. The purpose of this paper is to briefly outline the Endangered Species Act's highlights, to explain the process whereby a species is determined to be either Endangered or Threatened, and to instruct herpetologists in how they may assist the Office of Endangered Species in the determination process as it relates to the protection of amphibians and reptiles.

The Endangered Species Act of 1973

The Endangered Species Act of 1973 (Title 16, U.S. Code, Sections 1531-1543) attempts to provide means whereby Endangered and Threatened species of wildlife and plants, and the habitat necessary to their survival, may be preserved. The Act does this in three principal ways: 1) by the prevention or strict regulation of collecting and trading of Endangered or Threatened species, 2) by providing means for protection of species' habitat, and 3) by insuring that the United States complies with international agreements to which it is a party. To accomplish these goals, lists of Endangered and Threatened wildlife and plants are compiled by the Office of Endangered Species. The Act also provides means to set aside habitat for these species, either through direct Federal purchase or by authorizing funds to individual states for conservation of endangered or Threatened species within their jurisdiction. In addition, all Federal agencies must insure that their activities will not harm species determined to be Endangered or Threatened. On an international level, the Act allows the U.S. government to assist foreign governments in conserving their Endangered and Threatened species. Prohibitions are set forth for the collecting and commercial use of Endangered and Threatened species and their products, and penalties are prescribed for violation of the Act. Penalties may be severe; if the Act is knowingly violated, fines of up to $20,000 and imprisonment of up to one year may be imposed for criminal acts. In addition, a reward of up to half of the civil penalty or fine paid (not to exceed $2500) may be given to anyone who gives information which leads to the conviction of a person who violates the Act's prohibitions.

Prohibitions regarding Endangered species are varied. Except by permit, one cannot collect ("take") an Endangered species in the territorial United States, its territorial seas, or on the high seas, nor can anyone sell or offer in interstate or foreign commerce any such species. It is illegal to import or export an Endangered animal or plant or to carry, transport, or receive in interstate or foreign commerce such an animal or plant. It is not, however, illegal to own a member of an Endangered or Threatened species. Prohibitions and restrictions apply to live animals, as well as parts, products, offspring, eggs, or to the dead body and its parts.

Exceptions to the restrictions imposed by the Endangered Species Act may be allowed by permit for scientific study or to undertake measures which will aid in the propagation or survival of the species. There are no exemptions to State, Territorial, or Federal agencies regarding the need to obtain permits, except as outlined under Section 17.21(c)(3) of 50 CFR Part 17 (40 FR No. 188, pp. 44412-44429). Permit applications must be submitted according to Federal regulations contained in Parts 13 and 17, CFR; these can be obtained by writing to the Director of the Fish and Wildlife Service. Once submitted, applications are published in the *Federal Register* and anyone interested may submit comments on the application for a period of 30 days, at which time a decision is made.

Section 3(4) of the Endangered Species Act defines an endangered species as "any species which is in danger of extinction throughout all or a significant portion of its range" and Section 3(15) defines a threatened species as "any species which is likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range." Restrictions which apply to an Endangered species may or may not apply to a Threatened species depending upon whether the Secretary of the Interior considers such restriction necessary and advisable. However, permit applications for a Threatened species do not have to be published in the *Federal Register.* Also, for Threatened species, State law restrictions or any other special prohibitions can be substituted for Federal restrictions if so specified in the final rulemaking as it appears in the *Federal Register.*

A species is determined to be Endangered or Threatened because of any of five criteria as specified by Section 4(a)(1) of the Act. These are: 1) its range or habitat is presently or potentially threatened with destruction, modification, or curtailment; 2) overuse for commercial, sporting, scientific, or educational purposes; 3) depletion through disease or predation 4) inadequate laws or regulations; and 5) other natural or manmade factors affecting its continued existence. When preparing proposals, these factors are directly assessed as to their importance in determining the status of a species.

Authority for the final decision is delegated by the Secretary of the Interior to the Director of the U.S. Fish and Wildlife Service and his decision is based solely on biological data. In addition, the input of States or Territories, interested persons and organizations, Federal agencies, and when involved, foreign nations, is considered during the rulemaking process.

Critical Habitat

Section 7 of the Endangered Species Act allows "Critical Habitat" to be designated by the Secretary of the Interior as that habitat necessary to the survival of an Endangered or Threatened species. Included in consideration of factors involved in such a determination are: 1) space for normal growth, movements, or territorial behavior; 2) nutritional requirements, such as food, water, minerals; 3) sites for breeding, reproduction, or rearing of offspring; 4) cover or shelter; and 5) other biological, physical, or behavioral requirements. A "Critical Habitat" proposal may only be made for species occurring within the United States or its Territories; it can be made directly with the initial proposal for Endangered or Threatened status or at a later time.

A determination of "Critical Habitat" not only allows protection of the species involved, but also the habitat it requires to survive. All activities involving Federal agencies, or supported by Federal funding, must insure that they will not jeopardize the survival of an Endangered or Threatened species or harm an Endangered or Threatened species' "Critical Habitat." Unless "Critical Habitat" is specified, this is not the case.

Petitions and Suggestions

Anyone may petition the Secretary that an amphibian or reptile, or indeed any plant or animal, whether full species, subspecies, or unique population (animals only), be placed on the list of Endangered and Threatened Wildlife. This is done by writing the Director, U.S. Fish and Wildlife Service, and indicating the reasons for proposing the species' addition to the list; the Act requires that substantial information to warrant a review must be included with petitions.

Suggestions requesting that the Office of Endangered Species review the status of a particular species are often received. However, many amphibians and reptiles may be candidates for Endangered or Threatened status and it would be extremely time-consuming for personnel at the Office of Endangered Species to review thoroughly the literature for each animal for which a suggestion is received. Therefore, careful, well prepared reports accompanying suggestions will most likely receive attention before letters which simply express concern about the plight of particular species. The reason for this is clear. For the last two years, the Office of Endangered Species has not had a full time herpetologist on its staff; herpetological matters have been handled by other specialists who are more often occupied with the status of species in their own particular fields. Although I am presently assisting the Office of Endangered Species with their herpetological material, my appointment is only temporary. Therefore, the more thoroughly that Endangered and Threatened species reports are written, the better the chance for quick administrative action.

When suggesting that an amphibian or reptile be placed on the Endangered and Threatened Wildlife List, it would be best to include information of the type listed below. While there is no set "formula," reports by George Drewry and Kirkland Jones for the Golden Coqui, Richard Philibosian for the St. Croix Ground Lizard, and Herbert Harris, Robert Simmons, and Lanny Wilson for the New Mexican Ridge-nosed Rattlesnake provide excellent examples for future Endangered or Threatened species reports. It is primarily from their reports that the outline listed below is drawn.

I. General Information

A. Present and past distribution.

B. Estimated numbers.

C. Ecological requirements; natural history.

D. Habitat : physiographic, botanical, zoological. Includes general considerations as well as specific (to scientific names) associations.

E. Systematic status - especially if there is some question regarding status or nomenclature.

F. Significance or special considerations. An example would be ovoviviparity in the Golden Coqui.

G. Breeding potential in captivity.

II. Reasons for Consideration

A. Range or habitat destruction or modification - past, present, or future.

B. Overuse for commercial, sporting, scientific, or educational purposes.

C. Depletion through disease or predation.

D. Inadequate laws or regulations.

E. Other natural or manmade factors affecting existence.

III. Additional Comments

A. Status warranted.

B. Recommendations for actions to enhance the survival possibilities of the species.

C. Critical Habitat recommendation - both verbal and on topographical maps, if available.

D. Any other pertinent remarks.

It is absolutely essential to insure that reports document with literature references or information from those most familiar with the species involved, any statements which are of immediate importance to the species status. It is not enough simply to express concern, even if the status of a species appears obvious; concern must be backed up by data.

Once a species has been determined to be a candidate for consideration and sufficient background data are available, a Proposed Determination as either Threatened or Endangered and an Environmental Impact Assessment are prepared by the Office of Endangered Species' staff. This Proposed Determination is then published in the *Federal Register*, at which time public comments concerning the proposal are solicited for a period of 60 days. At the end of this period, comments are assessed as to their biological information, and a final decision is made concerning the species. The final decision with regard to the status of a species is based solely on the biological information; the public comments serve as an added source for this information, not as a voting contest on whether a species should be determined or not. Final Determinations are also published in the *Federal Register*. In the future, notice of Proposed and Final Determinations of amphibians and reptiles as either Threatened or Endangered will be sent to interested parties in the herpetological community.

Convention on International Trade

As a party to the 1973 Convention on International Trade in Endangered and Threatened Species of Wild Fauna and Flora, the United States has listed certain species of amphibians and reptiles as Endangered in accordance with Appendix I of the Convention. Section 9(c) of the Endangered Species Act of 1973 provides that it is a violation of the Act to trade specimens of species contrary to the provisions of the Convention. Even if any such species proves not to be Endangered as specified by the Act, it would still be subject to the provisions of the Convention, especially as regards importation and exportation for commercial purposes.

Summary

In the past, there has been much confusion about the Endangered Species Act. Most confusion surrounds the collection (allowed only with a permit in most cases) of Endangered or Threatened animals and the preservation of their habitat (the Act does not prohibit the activities of private individuals on their own lands except for actual collection of specimens; only the activities of Federally financed operations may be restricted if they endanger habitat vital to an Endangered or Threatened species). It is hoped that this paper has cleared up some confusion. Additional questions may be directed to Mr. Keith M. Schreiner, Associate Director - Federal Assistance, Fish and Wildlife Service, U.S. Department of the Interior, Washington, D.C. 20240.

With increased knowledge of the provisions and limitations of the Endangered Species Act, it is to be hoped that the many amphibians and reptiles currently in need of consideration may receive the attention they deserve.

GEOGRAPHIC DISTRIBUTION

AMPHIBIAN AND REPTILE RECORDS AND RANGE EXTENSIONS FOR MEXICO. We report here new records of Mexican amphibians and reptiles presently in the collection of the senior author (EAL). Unless noted all specimens were collected by the authors.

AMPHIBIA

AMBYSTOMA TIGRINUM VELASCI. Neuvo Leon: EAL 4065 (5 ad.), EAL 4066 (28 larvae), 20.3 km W, 10.6 km N Dr. Arroyo at La Lajita on El Pequeno Road, 21 July 1975. Reported for Neuvo Leon but once before (Reese, 1971, J. Herp., 5 (1/2), and this is the second collection for this state. *CHIROPTEROTRITON PRISCA.* Coahuila: EAL 3577 (3 sp.), 17.9 km E San Antonio de las Alazanas, 22 July 1973; Ernest A. Liner and Richard M. Johnson; EAL 4011 (3 sp.), 14.5 km E San Antonio de las Alazanas, 16 July 1975. First salamanders reported for the state. *PSEUDOEURYCEA GALEANAE.* Nuevo Leon: EAL 3103 (14 sp.), Ojo de Agua at Pablillo, 17 July 1972; EAL 3105 (1 sp.), 13.7 km S Pablillo, 18 July 1972; EAL 3110 (2 sp.), 16.8 km S Pablillo, 18 July 1972; EAL 3789 (2 sp.), 3.4 km N El Orito, 17 July 1974; EAL 4031 (8 sp.), 13.9 km S Pablillo at Puerto de Cienguillas, 19 July 1975; EAL 4047 (2 sp.), 12.9 km N La Ascension, 19 July 1975. Known from three collections previous to this report (Taylor, 1941, Proc. Biol. Soc. Wash. 54:81-86; Walker, 1955, Occ. Papers Mus. Zool., Univ. Mich. 567; Reese, 1971, op. cit.). The localities listed here give further localities for Neuvo Leon. EAL 3789 constitutes the northernmost record to date. *BUFO COMPACTILIS.* Tlaxcala: EAL 868 (1 sp.), 3.4 km NW San Ildefonso Hueyotlipan, 8 July 1963; EAL 869 (8 sp.), 4.4 km SE Calpulalpan, 8 July 1963. Ernest A. Liner and Richard Whitten. First recorded for this state. *SCAPHIOPUS HAMMONDI MULTIPLICATUS.* Tlaxcala: EAL 866 (82 sp.), 3.9 km NW San Ildefonso Hueyotlipan, 8 July 1963; EAL 870 (1 sp.), 4.4 km SE Calpulalpan, 8 July 1963; Ernest A. Liner and Richard Whitten. First records for this state.

REPTILIA

KINOSTERNON FLAVESCENS FLAVESCENS. Nuevo Leon: EAL 4073 (1 sp.), 24.8 km S Dr. Arroyo, 21 July 1975. Most southern record of this turtle to be collected in the state. *EUMECES BREVIROSTRIS PINEUS.* Nuevo Leon: EAL 3388 (1 sp.), 12.9 km S Pablillo at Puerto de Cienguillas, 22 May 1973; Ernest A. Liner, Douglas A. Rossman and Robert L. Erwin; EAL 3583 (1 sp.), Arroyo Mesquital from Poterio Prieto to 7.7 km S, 24 July 1973; Ernest A. Liner and Richard M. Johnson; EAL 3795 (1 sp.), 7.9 km N San Juan de Mimbres, 17 July 1974; EAL 4032 (7 sp.), 13.9 km S Pablillo at Puerto de Cienguillas, 19 July 1975. The above records are new localities in the state and supplement those of Dixon (1969, Cont. Sci. L.A. Co. Mus. 168). *SCELOPORUS JARROVI OBERON.* Nuevo Leon: EAL 3765 (2 sp.), Laguna de Sanchez to San Isidro, 4.2 km E Laguna de Sanchez, 15 July 1974; EAL 3770 & 3772 (2 sp.), San Isidro to San Juan Bautista in Cañon San Juan Bautista, 15 July 1974; EAL 4089 (2 sp.), 4.2 km E San Isidro, 23 July 1975. Extends range east from Saltillo, Coahuila area approximately 64.5 km. *SCELOPORUS SPINOSUS SPINOSUS.* Nuevo Leon: EAL 3106 (2 sp.), 7.9 km N La Ascension, 18 July 1972; EAL 3107 (1 sp.), 16.0 km N La Ascension, 18 July 1972; EAL 3801 (1 sp.), 32.1 km S Galeana, 18 July 1974; EAL 3813 & 3814 (2 sp.), 6.1 km N La Ascension, 18 July 1974; EAL 3816 (4 sp.), 1.1 km N General Ignacio Zaragosa, 19 July 1974; EAL 3818 (1 sp.), 5.0 km N General Ignacio Zaragosa, 18 July 1974; EAL 3820 (2 sp.), 7.7 km N General Ignacio Zaragosa, 18 July 1974; EAL 3822 (1 sp.), 8.9 km N General Ignacio Zaragosa, 19 July 1974; EAL 3830 (1 sp.), 0.8 km N Mier y Noreiga, 20 July 1974; EAL 3834 (1 sp.), 9.0 km N Mier y Noreiga, 20 July 1974; EAL 4051 (1 sp.), 4.9 km N, 3.9 km SE La Ascension on La Caballada road, 19 July 1975; EAL 4061 (1 sp.), 5.6 km W Aramberri, 20 July 1975. Recorded but once in Nuevo Leon by Martinez (1967, Thesis, Universidad de Nuevo Leon) from Zaragosa. The above are further records for the state. *SCELOPORUS TORQUATUS BINOCULARIS.* Nuevo Leon: EAL 3599 (1 sp.), 8.7 km E Laguna de Sanchez in Cañon San Juan Bautista, 26 July 1973; EAL 3600 (1 sp.), 11.2 km E Laguna de Sanchez in Cañon San Juan Bautista, 26 July 1973; Ernest A. Liner and Richard M. Johnson; EAL 3764 (2 sp.), Laguna de Sanchez to San Isidro, 4.2 km E Laguna de Sanchez, 15 July 1974; EAL 3769 (3 sp.), San Isidro to San Juan Bautista in Cañon San Juan Bautista, 15 July 1974; EAL 3773 (12 sp.), San Juan Bautista to La Cienega in Cañon San Juan Bautista, 15 July 1974; EAL 4084 (6 sp.), 2.1 km E and to San Isidro, 23 July 1975. Recorded from Mexico only from the vicinity of Galeana and Arroyo Mesquital. These records extend range in Nuevo Leon approximately 63.0 km NNW of Galeana. *CROTALUS SCUTULATUS SCUTULATUS.* Nuevo Leon: EAL 4057 (1 sp.), 5.6 km W Aramberri, 20 July 1975. Recorded but twice for Nuevo Leon (Liner, 1964, Southwest. Natur. 8(4); Reese, 1971, op. cit.).The above is a new locality and fifth specimen reported for the state. *LAMPROPELTIS MEXICANA ALTERNA.* Nuevo Leon: EAL 4022 (1 sp.), 2.9 km W, 5.3 km S San Antonio de las Alazanas, Coahuila, 17 July 1975. This specimen represents the sixth for Mexico and the second for Nuevo Leon (Gehlbach, 1967, Cat. Amer. Amphib. Rept., 55.1).

Submitted by ERNEST A. LINER, 310 Malibou Blvd., Houma, La. 70360, RICHARD M. JOHNSON, 4170 Lantern Lane, Mobile, Ala. 36609 and ALLAN H. CHANEY, 1208 W. Richard, Kingsville, Texas 78363.

TESTUDINES

CHRYSEMYS PICTA BELLI (Western Painted Turtle). U.S.A., Oklahoma, Kay Co., 10 km NW Braman; 5 Aug. 1976 (shell and dry limbs); 6 Aug. 1976 (alive); Jody Trott and Larry Miller. Collection of R.L. Lardie, RLL 1439 (to be deposited in the Univ. of Kansas collection) and collection of Larry Miller, alive. Establishes presence in Oklahoma. Nearest recorded populations are in Harper Co., Kansas (Collins, 1974, Amphibians and Reptiles in Kansas, Univ. Kansas Publ. Mus. Nat. Hist.). Submitted by LARRY MILLER, Caldwell Elementary School, Caldwell, Kansas 67022 and RICHARD L. LARDIE, School of Biological Sciences, Oklahoma State University, Stillwater, Oklahoma 74074.

TERRAPENE ORNATA ORNATA (Ornate box turtle). U.S.A., Illinois, Woodford Co., 1.5 km S Spring Bay on Ill. Hwy. 26; 15 June 1975; D. Moll, J.K. Tucker. Identified by D. Moll and released. First record from county and extends range about 80 km N of nearest previous record on E side of Illinois River (Smith, 1961, Illinois Nat. Hist. Surv. Bull. 28(1):1-298). Fayette Co., 5 km E St. Elmo at Jct. of Ill. Hwy. 128 and Penn Central RR; 3 May 1975; D. Moll, J.K. Tucker. Collection of J.K. Tucker, JKT-66. First record from county and extension of range 14 km E of nearest record in Effingham Co. (Smith, Op. cit.). Submitted by DON MOLL and JOHN K. TUCKER.

SERPENTES

CEMOPHORA COCCINEA COPEI (Scarlet snake). U.S.A., Texas, Sabine Co., Sabine National Forest, 22.5 km SE Hemphill; 6 June 1975; T.W. Lewis, Jr. and J.C. Kroll. Stephen F. Austin State University, School of Forestry, SFAWC 21 H. Jefferson Co., 4.8 km N Beaumont; 18 July 1975; J. Ashcraft. T.W. Lewis, Jr. Collection of J. Ashcraft, alive and uncatalogued. Jasper Co., 3.2 km N Jasper; 17 Sept. 1973; T.W. Lewis, Jr., J.R. Dixon. Texas A&M University, TCWC 48409. Jasper Co., Jasper city limit on Hwy 190 W.; 15 July 1974. Joe Wells. T.W. Lewis, Jr. Not retained. Newton Co., 3 km W Burkeville; 23 Sept. 1973; S.F. Holms. J.R. Dixon. Texas A&M University, TCWC 48410. All are county records extending range into mid-East Texas (Raun and Gehlbach, 1972, The Dallas Museum of Natural History, Dallas, Texas, Bull. 2). Submitted by TEAIRL W. LEWIS, JR., School of Forestry, Stephen F. Austin State University, Nacogdoches, Texas 75961, and JAMES R. DIXON, Dept. of Wildlife and Fisheries Science, Texas A&M University, College Station, Texas 77843.

ELAPHE GUTTATA GUTTATA (Corn snake). U.S.A., Kentucky, Hart Co., 4.8 km E Bonnieville; 11 May 1975; B. Bloomer, R.E. Todd, Jr. Collection of R.E. Todd, Jr., RET 210. Extends range 22.5 km N of previous record and supplements records in Collins (1970, Trans. Kentucky Acad. Sci. 31(1-2):49-50). Submitted by ROBERT E. TODD, JR., Rt. 1, Box 90-B, Sonora, KY 42776.

CAUDATA

AMBYSTOMA TIGRINUM VELASCI. (Plateau tiger salamander.) Mexico, Zacatecas, 2.7 km S Trancoso; 13 July 1974; Ernest A. Liner and Harold A. Dundee. Ernest A. Liner private collection, EAL 1169. First record for a salamander from the state of Zacatecas (Smith and Taylor, 1948, Bull. USNM., #194; Gehlbach, 1967, Cat. Amer. Amphib. Rept., 52.1). Submitted by HAROLD A. Amphib. Rept., 52.1). Submitted by HAROLD A. DUNDEE, Department of Biology, Tulane University, New Orleans, LA 70118 and ERNEST A. LINER, 310 Malibou Blvd., Houma, LA 70360.

PLETHODON CINEREUS (Red-backed salamander). U.S.A., Illinois, Wabash Co., 7 km ESE Mt. Carmel at Beall Woods State Park; 5 June 1976; D. Moll, J.K. Tucker. Collection of J.K. Tucker, JKT-65. First record for county and extension of range 35 km E of nearest record (Highton, 1962, Bull. Florida State Mus. 6(3):235-367) and 93 km S of Crawford Co. records (Smith, 1961, Illinois Nat. Hist. Surv. Bull. 28(1):1-298). Submitted by DON MOLL and JOHN K. TUCKER, Department of Biological Sciences, Illinois State University, Normal, Il. 61761.

SALIENTIA

HYLA AVIVOCA AVIVOCA (Western Bird-Voiced Tree Frog). U.S.A., Arkansas, Pope Co., 8.4 km NE Atkins; 23 April 1976; Glyn Turnipseed and Bruce Shackleford; Arkansas Polytechnic College Collection, No. 58. Verification by and additional specimen deposition to Dr. Ronald G. Altig, Dept. of Zoology, Mississippi State University, Mississippi State, Mississippi. Specimen deposition also to Dr. R.G. Zweifel, Dept. of Herpetology, American Museum of Natural History, AMNH 92872. First record for Arkansas. Nearest population on record is 226 km SW in McCurtain Co., Oklahoma (Blair and Lindsay, 1961, Southwest. Natur. 6(3-4):202). The Pope Co., Arkansas population was found in a Tupelo Gum-Bald Cypress (*Nyssa aquatica-Taxodium distichum*) association. The association may represent the western-most edge of the range for Tupelo Gum. Other anurans calling near *H.a. avivoca* were *Rana catesbeiana*, *R. utricularia*, *Acris crepitans blanchardi*, *Bufo woodhousei fowleri*, and *Hyla versicolor*. *H.a. avivoca* has also been heard at other locations in the vicinity but no specimens

have been collected to date. We suspect other populations of *H. a. avivoca* occur in Arkansas. Submitted by GLYN TURNIPSEED, Dept. of Biology, Arkansas Polytechnic College, Russellville, AR 72801.

SHORT REPORT

NEW RECORDS FOR AMPHIBIANS AND REPTILES FOR THE DEPARTMENT OF COLON, HONDURAS. During the course of field work around Trujillo, Depto. Colon, Honduras, we have amassed a number of new departmental records which add to those reported by Meyer and Wilson (1971, Los Angeles Co. Mus. Contrib. Sci., no. 218; 1973, Los Angeles Co. Mus. Contrib. Sci., no. 244) and Wilson and Meyer (in press, The snakes of Honduras, Ralph Curtis Publications, Hollywood, FL). Catalog numbers refer to author's field numbers.

New records: *HYLA STAUFFERI*- ca. 6 km NE Trujillo (DEH 12052); *PHRYNOHYAS VENULOSA* - ca. 4 KM W Trujillo (DEH 11650); *GYMNOPHTHALMUS SPECIOSUS* - ca. 3 km E Trujillo (DEH 12023-24); *LEPIDOPHYMA FLAVIMACULATUM* - Mts. above Trujillo (DEH 12020); *BOA CONSTRICTOR* - Trujillo (LDW 4550); *ELAPHE TRIASPIS* - Mts. above Trujillo (DEH 12031); *ENULIUS FLAVITORQUES* - Rio Grande, ca. 1 km W Trujillo (LDW 4549); *OXYBELIS FULGIDUS* - ca. 2 km E Trujillo (LDW 45710), ca. 7 km E Trujillo (LDW 4572); *TRETANORHINUS NIGROLUTEUS* - Barrio Rio Negro, Trujillo (DEH 12000, 12002, 12034; LDW 4577-4582).

Submitted by DONALD E. HAHN, Marcus J. Lawrence Memorial Hospital, Cottonwood, AZ 86326 and LARRY DAVID WILSON, Division of Intercurricular Studies, Miami-Dade Community College, South Campus, Miami, FL 33176.

NEW DISTRIBUTIONAL RECORDS FOR REPTILES FROM HONDURAS. During the course of field work designed to survey the flora and fauna of Honduras, various faculty members and students of the Departamento de Biologia, Universidad Nacional Autonoma de Honduras (UNAH), Tegucigalpa, D.C., Honduras have added to the University's collections a number of specimens of reptiles representing new distributional records. These supplement the information provided by Meyer and Wilson (1973, Los Angeles Co. Mus. Contrib. Sci., no. 244:1-39), Wilson and Meyer (in press, The snakes of Honduras, Ralph Curtis Publications, Hollywood, Florida), and Hahn and Wilson (in press, Herp. Rev.).

Range extensions: *SCELOPORUS SQUAMOSUS.* Potrerillos, Depto. Cortes; 14 April 1975; E. Vargas. M. Eraso. UNAH 5279. New record for the department and range extension of 103 km N of nearest record in Comayagua Valley to the southern end of the Sula Plain. *CNEMIDOPHORUS LEMNISCATUS.* Brus Laguna, Depto. Gracias a Dios; 25 January 1976; G. Cruz. J. Espinosa. UNAH 5386. First record for department and range extension of 157 km E of nearest record at Trujillo into the Mosquitea of Honduras. *TRETANORHINUS NIGROLUTEUS.* Brus Laguna, Depto. Gracias a Dios; 26 January 1976; G. Cruz. J. Espinosa. UNAH 5371. New record for department and range extension of 157 km E of nearest record at Trujillo into the Mosquitea of Honduras.

New departmental records: *CNEMIDOPHORUS DEPPEI.* La Paz, Depto. La Paz; 23 February 1976; G. Cruz. J. Espinosa. UNAH 5227. *CONOPHIS LINEATUS.* Magdalena, Depto. Intibuca; 5 January 1973; Jose Romulo Martinez. UNAH 5090. *DRYADOPHIS DORSALIS.* Yamaranguila, Depto. Intibuca; 27 June 1974; Jose Romulo Martinez. UNAH 5010. *GEOPHIS HOFFMANNI.* Mata de Maiz, Depto. Colon; 3 May 1975; G. Cruz. J. Espinosa. UNAH 5358. *HYDROMORPHUS CONCOLOR.* Nr. San Pedro Sula, Depto. Cortes; 15 April 1975; collector unknown. UNAH 5045.

Submitted by LARRY DAVID WILSON, Division of Intercurricular Studies, Miami-Dade Community College, South Campus, Miami, FL 33176, BECKY MYTON, and GUSTAVO CRUZ, Departamento de Biologia, Universidad Nacional Autonoma de Honduras, Tegucigalpa, D.C., Honduras, Centro America.

AMPHIBIANS AND REPTILES FROM JEKYLL ISLAND, GLYNN COUNTY, GEORGIA. From 30 June to 6 July 1975, we collected or observed twenty species of amphibians and reptiles on Jekyll Island. Thirteen species were not previously reported by Hillestad (1974, Annotated list of amphibians and reptiles of the coastal islands of Georgia. IN Johnson, A.S., H.O. Hillestad, S.F. Shanholtzer, and G.F. Shanholtzer. An ecological survey of the costal region of Georgia. Nat. Parks Ser. Sci. Mono. Ser. No. 3:XV+233 pp.). Specimens deposited in the collection of Rutgers University in Newark are designated RUN, others were captured, identified and released.

AMPHIBIANS: *Bufo terrestris* (RUN 4160), found throughout the island; *Limnaoedus ocularis*, called from ditches, rain pools and ponds throughout the island; *Hyla femoralis* (RUN 4150), restricted to the pine woods in the center of the island; *Gastrophryne carolinensis* (RUN 4145), called from ditches and flooded fields throughout the island; *Rana catesbeiana*, resident in large permanent ponds on the Golf Course in the center of the island; *Rana utricularia* (RUN 4139), found throughout the island.

REPTILES: *Ophisaurus ventralis* (RUN 4152), a single individual was found drowned in a flooded field in the center of the island; *Coluber constrictor,* a DOR was found on the southern tip of the island; *Elaphe guttata* (RUN 4158), found throughout the island; *Natrix fasciata*, one DOR was identified from the southern end of the island; *Thamnophis sauritus* (RUN 4153), several were taken at the southern end of the island; *Thamnophis sirtalis* (RUN 4156), found throughout the island.

Submitted by JAMES D. ANDERSON, SUSAN L. ANDERSON, KEITH A. HAWTHORNE, and SALOME C. LITWIN, Dept. of Zoology, Rutgers University, Newark, NJ 07102.

Thamnophis butleri (Butler's Garter Snake). Canada, Ontario, Dufferin Co., East Luther Township, E shore of Luther Lake. 4 August 1974. H.M. Karstad, P.A. Westell, and F.W. Schueler. To be deposited in National Museum of Canada, FWS 4829 -- 4832. 3 females and 20 young born in captivity. Northeasternmost Ontario record by 215 km. The adults appear somewhat intermediate between *T. butleri* and *T. brachystoma* as follows:

	Upper Labials Left	Right	Dorsal Scale Rows
*T. butleri**	7	7	19-19-17
FWS 4830	7	7	17-17-17
FWS 4831	7	7	19-18-17
FWS 4832	7	6	19-17-17
*T. brachystoma**	6	6	17-17-15

*Conant, R. 1950. Bull. Chicago Acad. Sci. 9:71-77.

Canada, Ontario, Kent Co., Walpole Island. 8 June 1971. F.W. Schueler, J.D. Rising, M.A. Telford, and B. Savan. NMC 16240. Gravid female; skeleton and viscera, skin lost by fire.

Submitted by FREDERICK W. SCHUELER and PAUL A. WESTELL. Dept. of Zoology, Univ. of Toronto, Toronto, M5S, 1A1, Ontario, Canada.

HERPETOLOGY'S LOSS

Isabelle dePeyster Hunt Conant died 3 November 1976 in Albuquerque, New Mexico, of multiple myeloma, after a long illness. She was the first woman photographer on the staff of any zoo, and she served in that capacity at the Philadelphia Zoological Garden for ten years during the period from 1943 to 1953. Her pictures of animals appeared in newspapers and other publications throughout the world, and because of her husband's interest in herpetology she took many thousands of photographs of reptiles and amphibians, hundreds of which were used in the publications of scores of scientists and in Dr. Conant's books.

Her greatest contribution was the art work for her husband's *Field Guide to Reptiles and Amphibians of Eastern and Central North America*, the second edition of which contained more than 1,000 illustrations. About half of these were reproductions of photographs, which she hand-colored from life to insure that the often brilliant hues of the frogs, salamanders, turtles, lizards, and snakes were reproduced with complete fidelity.

Mrs. Conant was born in Staten Island, New York, on 17 May 1901. For several years she served as a reporter for the Staten Island Advance, and in 1936 she joined the staff of the newly built Staten Island Zoo as its business manager and publicity director. In 1942 she transferred to the Philadelphia Zoological Garden.

She is survived by her husband, Dr. Roger Conant, Adjunct Professor at the University of New Mexico and Director Emeritus of the Philadelphia Zoo, and by many nieces and nephews.

Gifts may be sent to the American Cancer Society.

BOOK REVIEW

More on Nessie: A review of THE MONSTERS OF LOCH NESS (Roy P. Mackal: 1976; Swallow Press, 401 pp. $12.50) and THE LOCH NESS STORY (Nicholas Witchell: 1975; Penguin Books, 156 pp. $1.95).

Stories and books on Nessie exist in superabundance. No other animal or, if you prefer, phenomenon has had so much written about it with so little evidence. Most Nessie books bombard the reader with observational data, so presented to convince you that the Loch Ness monsters are giant worms, pleisosaurs, long-neck seals, or whatever strikes the author's fancy. These two books are striking exceptions, particularly in view of the news extravaganzas of this past year.

Witchell relates the history of the search for Nessie from its beginnings in the summer of 1934 to the partial success of last summer, 1975. The style is anecdotal but informative. The stories and observations are not new but Witchell's style and organization creates a highly readable and delightful book. The book recommends itself, in that it presents the evidence without promulgating a pet theory on the monster's identity.

Mackal's book is the first attempt to objectively analyze the mass of observational, photographic, and sonar evidence and to retain only the best. The book is nearly equally divided into three sections (14 chapters) of text and twelve appendices of data. The first section tells of Mackal's hesitant entrance into the search in 1965 and his supervision of the Loch Ness Investigation Bureau's technical operations in 1966 to 1970. Section two is a survey and discussion of the three classes of data, and, in section three, these data are analyzed with the attempt to determine the most likely identity of Nessie. The appendices contain a variety of information from classification tables of candidate animals, summaries of previously unpublished limnological data, and, most importantly, a listing and evaluation of the major observational, photographic, cinematic, and sonar data. These latter appendices in conjunction with chapter two make this book a must for even the most casual student of Loch Ness.

In the analysis section, Dr. Mackal first lists the possible candidates (mammals, reptiles, amphibians, fish, worms, and mollusk); then he compares the morphology, behavior, and environment of the candidates with that of Nessie. On the basis of the analysis, he postulates that the Nessies are either large thick-bodied eels or aquatic amphibians "probably some evolutionary descendent of an embolomer." He favors the latter interpretation. Although his character analysis matrix does show that Nessie shares more characters with amphibians than any of the other animals, I do not believe equal weight can be given to all the characters, especially salinity tolerance. The Nessie population has to be derived from the sea, for 30,000 years ago Loch Ness was covered by a glacier. Speculations on the Nessie identity will cease only when we have had a chance to closely examine one. Mackal's speculation or hypothesis has the advantage, since it is based on an objective analysis.

Of the two books, I prefer Mackal's because of its emphasis on facts and analysis; however, I recommend both. Together, they provide a complete summary of the search for Nessie, its disappointments and its elations.

WANTED: INDIGO INFORMATION

IF YOU HAVE INFORMATION CONCERNING THE CURRENT STATUS OR CONSERVATION OF THE EASTERN INDIGO SNAKE AND ITS' HABITAT IN GEORGIA, YOU CAN HELP. THE GEORGIA NATURAL RESOURCES BOARD MAY LIST THE ANIMAL AS A PROTECTED SPECIES UNDER THE PROVISIONS OF THE ENDANGERED WILDLIFE ACT OF 1973. WRITE TO Mr. Joe Tanner, Commissioner, Georgia Department of Natural Resources, 270 Washington Street, S.W., Atlanta, Georgia. EXPRESS YOUR OPINION ON THIS IMPORTANT ISSUE, AND ASK THAT YOUR LETTER BE FORWARDED TO THE NATURAL RESOURCES BOARD.

The Society for the Study of Amphibians and Reptiles will hold its 20th annual meeting jointly with the Herpetologists' League at The University of Kansas in Lawrence on 8-13 August 1977. In addition to contributed papers, the meetings will feature: 1) a symposium on The South American Herpetofauna: Its Origin, Evolution, and Dispersal, with Implications for its Preservation involving 24 participants from 11 countries; 2) a special program on regional herpetological societies; 3) photographic, art, and live animal exhibits. Chairman of the local committee is William E. Duellman. Registration forms, calls for papers, and details of meetings will be mailed to all members in March.

NEOTROPICAL NEWS

The National Museum of Costa Rica is publishing a French-Spanish collection of papers on bromeliad biology, "Biología de las Bromeliáceas", volume one of the Natural History classics of Costa Rica series, edited by the Museum's director, Luis Diego Gómez.

The bulk of this volume consists of C. Picado's "The Epiphytic Bromeliads as a Biological Millieu" published as a facsimile. Picado's classic work (in French: Les Bromeliaceés Epiphytes Considerees Comme Millieu Biologique) occupied 146 pages and 28 plates of the Bulletin Scientifique France-Belgique in 1913. There are also two other short papers by Picado, reprinted from the Comptes Rendús of the Paris Academy of Sciences.

The book also features important previously unpublished papers; an introduction and review of the bromeliad fauna (exclusive of amphibians and reptiles) by Gomez and notes on the phytogeography and physiological ecology of Costa Rican bromeliads by Kathy and John Utley. Of herpetological interest is a paper by D.C. Robinson on the bromeliad amphibians and reptiles of Costa Rica, including the first description of *Hyla picadoi*, a frog which E.R. Dunn named after Costa Rican biologist Clodomiro Picado T.

This volume will consist of about 250 pages and will be available in July for US $8.00, postpaid, from: Museo Nacional de Costa Rica, Apartado 749, San José, Costa Rica, Central America.

IN THE NEWS

The US Department of the Interior has dropped plans to comply with one of the provisions of the Lacey Act of 1900, which was aimed at cutting imports of wild species that might take over habitat and food used by native animals. An example is the African clawed frog, formerly used in pregnancy tests. Thousands have been found thriving in a California reservoir.

Proposals drafted since 1974 to comply with the law were opposed by the pet industry, and were abandoned partly because the Interior Department would not have enough money or staff to enforce regulations. Fish and Wildlife Service Director Lynn Greenwalt said Congress should enact legislation to strengthen the Lacey Act and clarify the Department's authority to regulate imports of harmful species. Imports of exotic species have doubled between 1968 and 1971.

In Stockholm, Sweden, three poisonous snakes, a saw-scale viper (*Echis carinatus*), a tropical rattlesnake, (*Crotalus durissus*), and an Argentinian horned viper, were used as guards for the "Star of Lanka" a 392-carat Blue star sapphire worth $429,000 at an exhibition of precious stones.

"Snake expert" Olle Rosenqvist stated: "We selected the most poisonous, the most aggressive and the fastest snakes in the world for this job. Together, these three species form a lethal triangle impossible to crack. I put them on the edge of starvation for a week and they are in top shape right now, stuffed with poison. Each one of them is capable of seven fatal bites. With those three together, death is 100% certain within ten minutes.

UPI in the Los Angeles *Times*

Disturbed by the disappearance, from around its coasts, of the sea turtle, which once formed one of the basics of the Indian Ocean islanders' diet, Seychelles has called for an urgent conference of all the Indian Ocean nations. The survival of the sea turtle is a matter of emergency, according to Seychelles President James Mancham. In 1968 when it was still a British colony, Seychelles passed laws aimed at ensuring the survival of the turtles. The ban on turtle fishing lasted until last year when, as independence approached, the Seychelles Assembly lifted the ban. Since then, however, no turtles have been landed by fishermen for sale in Victoria, the capital. The Seychelles sacrifice, Mancham said, has been to the advantage of turtle fishermen off the coast of East Africa and the Island of Mauritius, where the markets were flooded with turtle meat.

Agence France-Presse in Milwaukee *Journal*

The Board of Supervisors of Santa Cruz County, just south of San Francisco, California, has just passed a series of residential regulations designed to save the Santa Cruz long toed salamander (*Ambystoma macrodactylum croceum*), one of six salamanders on the endangered species list. Under the new rules, the culmination of a seven year campaign to save the creatures, any residence in a designated square mile portion of the county with a retaining wall more than 100 feet long must have ramps built into the wall to facilitate the salamander's breeding migration. In addition, streets must have rounded rather than square curbs; hillside homes must be built on columnar supports instead of enclosed foundations and surrounding ground must be kept vegetated as cover.

British Botany Professor Tony Swain states that dinosaurs are extinct today mostly because they had very poor taste. Swain says that new findings indicate dinosaurs had almost no taste buds and therefore couldn't tell when they were eating poisonous plants, which evolved about the time dinosaurs disappeared. He adds that many dinosaur skeletons are found in contorted positions indicating they died from a painful stomach poison.

ZNS in Bloomington-Normal, Ill., *Morning Sun*

In the middle of a 20,000 acre oak and pine forest 25 miles from Houston, Texas developers are building a town, The Woodlands, that will eventually house over 100,000 people. It is the largest scale project to date in the 'urban wildlife' movement, and is designed to have the best of both worlds- the city and the country-within easy reach of everybody.

Several thousand acres are being left as undeveloped "open space". Trees are removed only on the precise spots slated for construction, and the natural ground cover of mulch, pine cones and dead leaves take the place of grass. As a result, armadillos, deer, pileated woodpeckers, rattlesnakes and other wildlife continue to inhabit The Woodlands, where 1,000 people already reside.

LOCH NESS MONSTER REPRINTS

Because of the poor quality of reproduction of photographs in the article on the Loch Ness monster (*Herpetological Review*, vol. 7, no. 2, June 1976), the author is making reprints available on high-contrast, glossy paper. Single copies can be obtained free-of-charge from Kraig Adler, Langmuir Laboratory, Cornell University, Ithaca, NY 14853

WANTED: All possible information on ratsnakes *Elaphe* for potential use in a monograph on the genus.

Contact:
John C. Zegel
Reptile Keeper
Atlanta Zoological Park
800 Cherokee Ave., S.E.
Atlanta, Georgia 30316

INFORMATION WANTED REGARDING EGG PREDATION IN *ANOLIS EQUESTRIS.* PLEASE WRITE HENRY COHEN, 24 ST. JOHNS PL., BUFFALO, NEW YORK 14201.

CATALOGUE OF AMERICAN AMPHIBIANS AND REPTILES

(Now published by the SSAR)

A loose-leaf series of 2- to 4- page species accounts of the amphibians and reptiles of the Americas, with special emphasis on those in the United States and Canada. Accounts 1-150 were published from 1963 to 1972.

Binder, Taxonomic Tabs, and Accounts 1-150

Individuals.....$25.00
INSTITUTIONS.....$35.00

Subscription to accounts 151-175 (*published through no.* 163 *to date*)

Individuals.....$ 6.00
INSTITUTIONS.....$12.00

Write:

ON TRANSPLANTING ALLIGATORS

I read with chagrin your report on the National Audubon Society's recommendation to transplant Louisiana alligators to other parts of the species' range (Herp. Rev. 6(4): 114). I am staff herpetologist for Massachusetts Audubon Society and nominally on the joint scientific staff with National Audubon Society. I was never consulted in this matter, deprecate the decision, and disavow all connection with it.

I am extensively familiar first hand with the alligator situation in Louisiana and adjacent states. The coastal marsh alligators are dramatically different from inland swamp alligators in behavior and breeding biology; the genetic basis for the differences is unproven, but certainly highly probable. It is in the coastal marshes that alligators are described as "overpopulated". I believe transport and release of coastal marsh alligators to other parts of the species' range, especially to inland swamps, will be at best a cruel way to kill alligators and at worst a catastrophe for natural patterns of geographic variation.

Alligators are doing very well in most parts of their former range where suitable habitat remains. Even in areas where habitat exists and they are rare, we can confidently expect the native stocks to rapidly recuperate. I doubt that alligators are "overpopulated" anywhere. In any case, harvesting "surplus" Louisiana marsh alligators - if properly controlled - could not hurt the species and might materially decrease demand for the hides of genuinely endangered tropical crocodilians.

Conservation agencies, like my own, are often dominated by highly altruistic, well-meaning individuals with a dearth of biological knowledge. Even at the Ph.D. level, ornithology is still larded with bird fanciers who actively support programs of introducing exotics. I believe herpetologists should behave more responsibly, and hope that SSAR will publicly oppose such programs in the future.

Sincerely,

James D. Lazell, Ph.D.
Scientific Staff

REPORT OF THE SSAR RESOLUTIONS COMMITTEE
(unofficial version)

Preamble: When Chairman Vial asked me to chair the Resolutions Committee, I went to an experienced hand at SSAR meetings for advice in drafting the resolutions statement and his advice was: "Keep it light and for God's sake, keep out the whereas's!" In an attempt to follow his advice, I have taken the Committee's recommendations and edited them with the result that the following is light to the verge of being vaporous.

Be it resolved that:

Whereas, (Sorry about that, but can you think of any other way to start? That's the only one, I promise) the 19th Annual Meeting of the SSAR at Miami University has been a most successful one, with over 300 paid attendance (and innumerable unpaid ones, herpetologists having long ago found that tightfistedness has high fitness), we resolve to extend our thanks and appreciation to the following people who made it all possible.

To the Local Committee: Co-Chairmen, Doug Taylor and Shelly Guttman. Registration, Lynne Lohmeier, Melinda Moore, Susan Small, Mali Hutchison, Sara Woolpy, and Neil Ford. (Note from Doug Taylor: Lynne, Melinda, and Susan are my undergrad secretaries who worked overtime to make this meeting a success. Thanks, girls.) Transportation, Al Karlin, Don Holzworth, and Jay Youngs. Social Hour, Karen Blackburn, Mike McCloud, Bob Yeager, Don Holzworth, and Bob Bard, a group of non-herpetologists who survived the onslaught of a group of drunken herpetologists -- to you, the Croix de Guerre! Also thanks to two unique people who belonged to both groups: Al Karlin and George Labanick! Gophers, Kevin Crofton and Tom Hill. (You don't know what a gopher is? As in, "Kevin, gopher a Carousel and set it up in the Heritage Room." Projectionists, Jill Auburn and Lyn Branch. Art Exhibit, Dave Dennis and the others who helped.

We would like to thank the Vice President of Alumni Affairs, John Dolibois, of the original Miami University (not to be confused with the Florida imitation), and all other representatives of the host institution for providing the facilities and pleasant environment in which to hold this meeting.

We would like to thank Ed Maruska, Director of the Cincinnati Zoo, and David Jardine, Curator of Reptiles, for their invitation to the members of the Society to visit the Zoo to see and photograph this excellent collection of amphibians and reptiles.

The program has been a most successful one. We would like to thank Tom Uzzell and all of the participants in the Symposium on Reproductive Biology of Amphibians which was useful, educational and most of all,interesting. (In turn, Tom has asked me to thank Miami University for financial support and Doug and Shelly for help above and beyond that usually provided by the Local Committee. And I certainly appreciated the "Ev and Charlie Show" provided by the amphibiologists from time to time!) We should also like to express our appreciation of all of the contributed papers (even when we disagreed with them!).

We would like to thank all of the officers and members of SSAR for the support that has made the programs of the Society so imaginative and successful, especially: Max Nickerson, retiring editor of Herp. Review, who has struggled with increasing content, increasing costs, and limited budgets, and our Treasurer, Henri Seibert, who has kept the Society in the black (and the Board of Directors in the dark) these many years. Personally, I would like to offer special thanks to the single retiring board member this year for his outstanding service, to...uh.... the name seems to be misspelled...

Finally, few people realize the task the chairmanship of SSAR involves. It is not a figure-head position. Jim Vial has literally worked his coccyx off... (he has the X-rays to prove it!) in advancing programs of the Society. He deserves our whole-hearted thanks. We extend to him our appreciation for a job well done. (Thanks, Jim.)

And lastly, but not leastly, I'm sure we all would like to thank those who provided the social lubrication at the Social Hour at Hueston Woods: Fisher Scientific, Corning Glass, and one or more person or persons unnamed who would prefer to remain unnamed!

(Turning to Jim Vial): Dr. Chairperson, I move the unanimous acceptance of this report!

Jim Huheey, for:
Ron Brandon, Rich Montanucci

ENVENOMATION IN SNAKES AND ITS TREATMENT WITH ANTIVENIN

On 13 December 1974 at the Baltimore Zoo, a 1.5 m, 360 g Blanding's tree snake (Boiga blandingi) was bitten by a 1.8 m black mamba (Dendroaspis polylepis). The mamba delivered a single quick strike to the tree snake's dorsolateral surface, near midbody, at 0902 h. Within 15 min the bitten snake was in obvious distress, lying inertly on its side with mouth open. Since the tree snake appeared to be in extremis it was felt that little could be lost by administering antivenin. At 0935, five ml SAIMR Polyvalent Antivenin (Bitis, Dendroaspis, Hemachatus, Naja) was injected IP. The dosage was selected arbitrarily. There was no change in condition until 1510 h when the tree snake was observed in a normal position with mouth closed. By 1600 h, when observation was ended for the day, it was moving sluggishly and occasionally flicking its tongue.

On the morning of 14 December the snake was still generally inactive, but showed no other signs of distress. During the night it had ejaculated 2- 3 ml of semen, possibly as a result of pressure generated by the relatively massive injection of antivenin into the body cavity in the general area of the testes. Thereafter gradual improvement was indicated by increased activity, although food was refused on 17 and 19 December. On 7 January 1975, the snake fed for the first time since the bite and, a month later, was on a regular feeding schedule, apparently fully recovered.

Since spontaneous recovery may have occurred in this case it was decided to test this possibility by allowing the mamba to bite another tree snake and to withhold antivenin. Thus, a second B. blandingi, a larger female from the same clutch of eggs as the first, was selected. This specimen was 2 m and weighed 502 g. It was disfigured by a number of calcium deposits along the vertebral column but was otherwise in apparent good health.

On 19 December 1974, at 0922 h the mamba was induced to bite this snake. The mamba had not fed, nor, as far as is known, expended venom in any other way since the time of the first bite. A single quick strike was delivered to the same body area as in the first specimen. Symptoms of envenomation, immobility, lateral recumbency and open mouth, were noted at 0945. Irregular respiration, as observed by the opening and closing of the snake's glottis, continued until 1215 h, when all signs of breathing ceased.

The death of the second snake does not prove, but strongly indicates, that antivenin therapy was an effective factor in the survival of the first.

TERRITORY AND HOME RANGE MAPPING FOR LIZARDS AND OTHER SMALL ANIMALS: A PHOTOGRAPHIC METHOD. --The estimation of lizard home range and territory sizes recently evoked considerable interest concerning sample size biases and area determinations after loci have been plotted (Milstead, 1971, 1972; Turner, 1971). Problems also arise at earlier stages of home range and territory size estimations when a decision must be made regarding the plotting of recapture, sighting, or defense loci. These records must allow areas to be calculated with a minimum of error and effort.

Traditionally, a grid system is established by staking the study area, mapping it on paper, and reproducing copies of the grid map. Recapture, sighting, or defense points are plotted on the grid maps. This method works well for many studies but is cumbersome for others. For example, a large patchy area which results in the patchy distribution of the experimental animals requires either a largely unused grid of enormous size or many small grids. Setting up a largely unused grid is inefficient and it may be very difficult if not impossible, to decide on locations for the small grids during the initial stages of the study. The grid system may also be awkward for an investigator using many areas for short periods of time. Staking each area requires time that might best be spent in other pursuits. Finally, grid systems invite inaccuracies because loci must be approximated on grid maps. Finer grids reduce error but can be difficult to establish and maintain.

While working on a study relating food abundance to territory size in the iguanid lizard Sceloporus jarrovi (Simon, in press), I encountered several of the above problems and shifted from a grid system to a photographic method. Territory defense points were plotted on Polaroid photographs. Photos were taken as needed and filed in a field notebook under the assigned number of each territorial animal. A maximum of 3 photos encompassed each lizard's territory; the scale used varied from photo to photo but allowed significant landmarks such as boulders and trees to be individually recognized. Since the scale varied, all distances were measured in the field by referring to the photos.

The disadvantages of this system are that home range or territory overlaps are not obvious and that basic measurements must be made in the field. I do not suggest the photographic method for all studies; the ecological questions each investigator asks must determine which method is best.

Funding during the development of this method came from the Chancellor's Patent Fund of the University of California at Riverside and field work was done at the American Museum of Natural History's Southwestern Research Station, Portal, Arizona.

COURTSHIP-LIKE BEHAVIOR OF IMMATURE TURTLES

There are few references to courtship-like behavior in young turtles in the herpetological literature. Thomas (1969) recorded it for young Testudo hermanni and Cagle (1955) reported titillation for hatchling Graptemys kohni, Pseudemys scripta, and P. floridana, and a Graptemys flavimaculata which "was in its first season of growth" but "retained many hatchling characteristics." He suggested that the premating activity display in immature turtles might serve as a means of identification since he observed it only when a turtle encountered a foreign organism for the first time.

On 21 September 1971 titillation was observed between two juvenile Pseudemys scripta elegans. The sliders had shared the same aquarium since their acquisition from a commercial dealer in the summer of 1970. Both turtles were about 5 cm in carapace length, but one was slightly larger than the other. The larger turtle (a male) approached the smaller one (sex undetermined), extended its forefeet, and vibrated its nails against the other's head. The smaller turtle attempted to turn and swim away, but the larger scripta again took a position facing its cagemate, and performed another titillation bout. On this occasion the smaller chelonian did not seek escape, but instead returned the titillation action. Then both turtles turned and swam in opposite directions. Neither turtle was ever observed to "court" two Podocnemis unifilis or a Chelydra serpentina in the same aquarium.

The observation of titillation between immature turtles which were familiar with each other suggests that courtship-like display in juvenile emydids may have a sexual significance in addition to serving an identification purpose. Perhaps in hatchlings (i.e., those turtles with less than one growing season completed) the primary purpose of such behavior is to serve as a means of communicating information about the turtle's environ, while in older juveniles the inception of hormonal release triggers such action. Cagle (1950) reported that male P. s. elegans may reach sexual maturity in less than two growing seasons; consequently it seems plausible that androgens may be released while a male turtle is still quite young (less than three years old). Therefore, both sensory and sexual releasers could be present at the same point in a turtle's development. The validity of this explanation is suggested by an instance on 23 July 1972, when the larger P. s. elegans noted above approached a food item (a small bluntnose minnow, Pimephales notatus) and vibrated its claws against the fish before devouring it. Although the reptile's main diet consisted of fish, most of the food was presented after it had been frozen and thawed; the Pimephales was fresh, and could have been a novel enough stimulus to elicit the "courtship" display, even though the turtle had been fed fresh material on a few previous occasions.

Investigations aimed at determining when changes leading to sexual maturity in reptiles actually begin, coupled with studies on wild juvenile turtles to determine if, and under what conditions, they display the courtship patterns, would be very helpful in explaining precopulatory behavior of immature captive emydids.

Thanks are due Drs. P. W. Smith and L. M. Page for critically reading the manuscript. I also extend my appreciation to H. W. Greene for providing comments and bringing my attention to a pertinent literature reference.

ESCAPE BEHAVIOR OF THE SOUTHERN PLAINS SKINK

The Southern Plains Skink Eumeces septentrionalis obtusirostris is normally found among leaves and under logs in oak-woodland communities in Oklahoma (Webb, 1970). During May 1975 I observed an interesting escape behavior of these skinks in a grassy, open field on the Oklahoma Baptist University campus. The field surrounds a one-acre pond containing mats of aquatic vegetation and a muskrat population. Cattle graze the field and cave in the muskrat burrows which results in holes 15-40 cm in diameter, up to 3 m long and 15-30 cm in depth surrounding the pond.

Southern Plains Skinks were observed disappearing into the holes and burrows. When a skink was disturbed and prevented from entering a burrow, it usually ran onto the matted vegetation in the pond. Skinks showed no hesitation in entering the water, running onto surface vegetation or even swimming under the aquatic vegetation. Some skinks were located over 2 m from shore.

Taylor (1936) reported that two E. s. obtusirostris took to water to escape when disturbed. Similar behavior has been reported for Scincella lateralis (Collins, 1974; Smith, 1946), Eumeces inexpectatus and Eumeces multivirgatus gaigeae (Smith, 1946).

An Eumeces septentrionalis utilizing aquatic vegetation as an escape medium.

THAMNOPHIS ELEGANS CAPTURES SOREX EMARGINATUS-- Small mice, especially Microtus, are known food items of Thamnophis elegans (Fitch, California Fish and Game, vol. 27, 1941; White and Kolb, Copeia, No. 1, 1974) as well as of Thamnophis sirtalis (Fitch, Univ. Kansas Publ. Mus. Nat. Hist., vol. 15, 1965). However, the use of shrews as food by garter snakes is seldom reported; Hamilton (Amer. Midl. Nat., vol. 46, 1951), found Blarina brevicauda as a food item of T. sirtalis, and Grinnell, Dixon, and Linsdale (Univ. California Publ. Zool., vol. 35, 1930) noted T. elegans eating an unidentified shrew. Since the food habits of T. elegans in Mexico are little known, the following snake-shrew relationship seems worthy of record.

On 4 August 1975, our field party made a stop in montane pine-oak habitat in the Sierra Madre Occidental (at 2900 m) about 10 km (airline; approximately 19 km by winding mountain road) west of San Juan Capistrano, Zacatecas. This locality in west-central Mexico is just at the boundary between southwestern Zacatecas and extreme southern Durango and less than 5 km north of where the boundaries of these two states meet that of Nayarit.

At about 1630 hours we were looking for vertebrate signs in mixed grass and forbs along the border of a cornfield being cultivated by a family of Tepehuan Indians. When probing a small pile of brush, a garter snake, T. elegans, moved out from the opposite side of this debris. In its mouth securely held in a crosswise position was a shrew, which proved to be a lactating female Sorex emarginatus Merriam. The prey was covered with snake saliva from head to the hips. Thus, it was presumed that our presence had prompted the garter snake to regurgitate the partly-swallowed shrew, then pick it up and attempt to escape. Both specimens were preserved; the snake (RGW no. 6386) is a female with a body length of 482 mm in the R.G. Webb Collection and the shrew (MSU no. 23482) in The Museum at Michigan State University. The authors appreciate the field assistance of Stuart E. Knapp of Oregon State University and Mary W. Baker, and the cooperation of Mario Luis Cossio G., Director General de Fauna Silvestre, Departamento de Conservacion, Estados Unidos Mexicanos, for making permits available for our field studies.

Herpetological Circulars, edited by George R. Pisani (Biology Dept., Univ. of Kansas, Lawrence, KS 66045) publishes miscellaneous manuscripts which will be of value to the general herpetological community and segments of the public-at-large. Titles published thus far include A Guide to Preservation Techniques for Amphibians and Reptiles (English and Spanish editions), Collections of Preserved Amphibians and Reptiles in the United States, and A Brief Outline of Suggested Treatments for Diseases of Captive Reptiles. Persons having manuscripts or ideas for manuscripts which are 1) between 15 and 80 typed pages (dbl. space) long, not counting illustrations, 2) of general interest, and 3) do not present research articles better included in The Journal of Herpetology are encouraged to contact the Circulars editor.

PREDATION ON IGUANID LIZARDS BY THE ROUNDTAIL CHUB, GILA ROBUSTA GRAHAMI, AT FOSSIL CREEK, ARIZONA

During analysis of stomach contents of Gila robusta grahami, it became apparent that this species was an opportunistic feeder like other members of his genus (Venicek and Kramer, 1969). They consume both aquatic and terrestrial organisms. Two terrestrial iguanid lizards (Urosaurus ornatus and Sceloporus clarki) were taken during the 17 October 1975 collection of fish at Fossil Creek, Gila County, Arizona. The adult Urosaurus was in the stomach of a chub measuring 181 m in total length , and weighed 61 gm, while the fish that consumed the hatchling Sceloporus was 169 mm in length and weighed 42 gm. The tree lizard measured 37 mm SVL and weighed 2.1 gm while the Clark's spiny lizard was 39 mm SVL and weighed 3.2 gm.

The occurrence of lizards as food items of fish seems to be extremely rare since only two lizards were found in 453 stomachs from Fossil Creek chubs. It seems probable that larger fish would take lizards if available in their microhabitat since most fish are omnivores (Minckley, 1973).

According to Stebbins (1972) both Urosaurus and Sceloporus may be found in riparian situations which would increase the chances of a lizard entering the water. Lizards may enter water to avoid predators (Dillon and Baldauf, 1945) or possibly in search of "preferred food items". Since the Sceloporus had recently-ingested dragonflies in its stomach it is possible that it had been feeding along the stream when it either fell in or was actively taken by the fish.

ACKNOWLEDGEMENTS

I thank Dr. Oliver Johnson for lizard identification, assisting in the literature search, and helpful suggestions. Also I thank Mr. C.O. Minckley for helping with the October collections and supplying helpful suggestions. The Arizona Public Service and the Forest Service provided access to Fossil Creek.

Newtown, Pennsylvania 18940

Lampropeltis triangulum elapsoides. In September 1974, a gravid scarlet king snake, *Lampropeltis triangulum elapsoides* (ca. 425 mm snout-vent) was collected near Miami, Dade County, Florida. On 8 October 1974, it laid 5 eggs. When first noticed, three of the eggs had been deposited. The last two eggs were laid at 17 and 48 min. intervals. The five eggs were 23.2 - 30.2 mm (mean 27.3 mm) in length, and 9.6 - 11.8 mm (mean 10.8 mm) in diameter. Their weights ranged from 1.5 - 2.3 g (mean 1.9 g).

The eggs were incubated in a plastic box containing moist substrate (Vermiculite) at 25 - 28 C. By 13 November, 4 eggs had spoiled and appeared to have been infertile. On 7 December, the remaining egg was found to have increased slightly in size and weight. On 12 December, the shell seemed very thin and movements of the developing young were observed. Several days later the egg collapsed and was opened. It contained a fully-developed dead snake, which was ca. 150 mm total length.

This clutch of eggs was produced at a late date. Reproductive data for this subspecies indicates that egg laying occurs in June - July and hatching in August - September (Williams, K. L. 1971. Systematics of the colubrid snake *Lampropeltis triangulum* Lacepede. Univ. Microfilms, 6617, 371 p.; Groves, J. D., and P. S. Sachs. 1973. Eggs and young of the scarlet king snake, *Lampropeltis triangulum elapsoides*. J. Herp. 7(4): 389-390). Perhaps, in the southern portions of its range, the scarlet king snake produces more than one clutch of eggs in a season or some intrinsic or extrinsic factor forced this individual to reproduce aberrantly.

OWL PREDATION ON AMBYSTOMA TIGRINUM

A pellet taken under the perch of a Great Horned Owl (*Bubo virginianus*) from six miles north of Ogallah, Trego County, Kansas, 20 July 1975 by J. A. Holman, contained the skeleton of an adult *Ambystoma tigrinum*, presumably the subspecies *A. t. mavortium* (Collins, 1974). The skeleton was identified using the criteria of Holman (1975, p. 51). The pellet also contained beetle and mouse remains. This record is interesting in the light of numerous *Ambystoma tigrinum* fossils from North American Pleistocene caves and rock ledges, as it suggests the possibility of transportation there by owls.

EARLY EGG DEPOSITION BY THE SOUTHERN BLACK RACER, *COLUBER CONSTRICTOR PRIAPUS*

A female southern black racer was captured on 11 March 1975 six miles south of Bradley Junction, Polk Co., Florida. This snake, measuring 910 mm (S-V), deposited a clutch of 14 eggs in captivity 5 days later on 16 March 1975. The eggs were all in excellent condition and averaged 32.4 mm in length (28.7-34.5) and 21.3 mm in width (18.7-22.6). Incubation was achieved in a plastic box filled with sphagnum moss at 26-27°C and 9 of the 14 eggs hatched on 21 June 1975. The eggs were maintained in my home without the use of an incubator or environmental chamber. The seven male hatchlings had an average S-V length of 217 mm (182-258) and an average total length of 290 mm (246-345). The two female hatchlings had an average S-V length of 230 mm (212-248) and an average total length of 305 mm (289-322).

The clutch deposition by this individual was quite early, considering that Wright and Bishop (1915), Cagle (1942) and Rossman (1960) have recorded 19 June, 10 June and 1 June, respectively, as dates of laying for *Coluber constrictor priapus*. The earliest record for any snake of this species is for *C. c. flaviventris* with a laying date of 1 June (Ortenberger, 1928).

The early clutch deposition is coupled with an incubation time of 97 days, more than one and a half times as long as previous records. Fitch (1963) has shown that previously the longest incubation period for *C. c. priapus* is 59 days and the longest for any snake of this species is 73 days in *C. c. stejnegerianus*.

It is conceivable that the eggs would normally have been held until a later date if the snake's capture had not intervened. Fitch (1963) states that gravid females produced a clutch of eggs within a few days after having been brought into captivity. The occurrence described indicates that the eggs are ready for deposition at least a few days in advance of the actual laying date which gives the female sufficient latitude in locating a suitable nest site. This also appears to suggest that *C. c. priapus* has the potential for producing more than one clutch per year, although Fitch (1970) did not report evidence for this in *Coluber*.

NOTES ON EGGS AND HATCHLINGS OF XENOCALAMUS BICOLOR LINEATUS ROUX FROM SOUTH AFRICA

The genus Xenocalamus belongs to the African colubrid subfamily Aparallactinae, and currently contains 5 species and 9 forms (Broadley, 1971). Snakes of the genus are small (although one species, X. michelli, reaches a length of over 1 m), fossorial, and characterized by an elongate body, small head and obtusely to acutely pointed snout from which their popular name, quill-snouted snakes, is derived.

Knowledge concerning reproduction in the genus is sparse and restricted to egg measurements (X. bicolor lineatus lays three to four eggs measuring up to 26 x 6 mm), FitzSimons, 1962; X. transvaalensis "contained two eggs measuring 28 x 6 mm", Broadley, 1971). We report here the first record of incubation of Xenocalamus eggs, with details of size, weight and lepidosis of hatchlings.

A female Xenocalamus bicolor lineatus Roux of record length (505 + 34 mm), collected in the vicinity of Celine, northern Transvaal, South Africa, was received at the Transvaal Snake Park on 13 December 1974. On 7 January 1975 the female laid four eggs which were ivory-colored, smooth-shelled and elongate in shape, with maximum lengths of 45, 45, 40 and 47 mm. These lengths are almost double those recorded for the subspecies by FitzSimons (1962). The diameters of the eggs were not recorded, but were approximately twice the diameter of the spent female, i.e., approximately 15 mm.

The eggs were incubated on moist paper towels in a Vosmar incubator maintained at 30-32°C. The first egg hatched on 3 March 1975, two more hatched on the next day, and the final hatchling emerged on 5 March 1975, giving an incubation period of 55-57 days. Sex ratio of the young was 1:1. Details of size, weight, and scutellation of the mother and hatchlings are shown in Table 1. All had divided anal scales. Ventrals were counted by the Dowling (1951) method. The subcaudals are divided and counts, recorded for both sides of the tail, begin with the first scute in contact with its fellow on the midline and exclude the terminal spine. One female hatchling (No. 2) had confused subcaudal scalation with paired, unpaired, fused and divided scutes, resulting in a large difference between counts on the right and left side of the tail. Scutellation details not recorded in Table 1., i.e., dorsal scale rows, head plates, etc., are as described for the subspecies X. b. lineatus by Broadley (1971).

Coloration of hatchlings was similar to that of the mother, and to that described by Broadley (1971) for southern populations of X. b. lineatus (Waterpoort, northern Transvaal), i.e., dorsal stripe broad (12 scales wide). However, the yellow lateral coloration was considerably reduced in the mother and absent in the hatchlings. No intraspecific color variation as described in X. b. bicolor (Broadley, 1971) was evident.

The hatchlings have low ventral counts, those of the two males being in the lower range of X. b. lineatus counts (198-234 in ♂♂). However, ventral counts in the two females are substantially lower than for X. b. lineatus (221-248 in ♀♀), falling into the range of the subspecies X. b. australis (205-216 in ♀♀). Celine is at the southern limit of the distribution of X. b. lineatus and borders the range of X. b. australis. It is thus possible that the low ventral counts of the female hatchlings reflects intergradation between the two subspecies. Lateral yellow coloration is absent in X. b. australis and the four hatchlings, although in the latter this may have developed later. The upper labial counts of the hatchlings and mother are typical of X. b. lineatus (i.e., six, the third and fourth entering orbit) and show no evidence of approaching the condition found in X. b. australis (i.e.,five, the third entering orbit).

Xenocalamus apparently prey exclusively on amphisbaenians (Broadley, 1971) and it thus proved impossible to maintain the mother or young. They were thus sacrificed for serological and chromosomal analysis, the results of which will be presented elsewhere (Branch, 1975). The mother and two of the hatchlings have been placed in the herpetological collection of the Transvaal Museum, Pretoria (TM 46130-2).

Northeastern Field Naturalists' Society

The NORTHEASTERN FIELD NATURALISTS' SOCIETY is an organization of professional, student, and amateur naturalists devoted to pure ecological research and biological conservation studies. Especial attention is given by the Society to the study of the natural animal and plant populations and communities of the northeastern United States and the influences of urbanization on wildlife in general. Although originally founded as the Long Island Herpetological Society in 1965, the NEFNS has evolved into a multidisciplinary organization that now consists of herpetologists, entomologists, ornithologists, botanists, mammalogists,and naturalists with primary interests in other fields. All interested persons are encouraged to join us.

PUBLICATIONS

A major aspect of the Society is its publications, and membership includes a subscription to all of these. With the belief that a well-rounded series of publications is better than a single journal, the Society provides its members with one of the most diversified series of natural history periodicals. Four regular periodicals are issued by the NEFNS, and no less than one number of each is published per year. The contents of these publications are so diverse that both long-established professional and beginning amateur naturalists will find much of value. All the back issues of current Society publications are available, and a price list will be furnished on request.

FACSIMILE REPRINT SERIES

The *Facsimile Reprint Series* provides members with long out-of-print papers on the natural history of the Northeast. Particular efforts are made to reprint papers that contain extremely relevant information but that have generally been overlooked by researching naturalists in the past.

ENGELHARDTIA

Engelhardtia is the more formal scientific journal of the Society. It is devoted to original analytical research papers. All papers are abstracted and reviewed for listing in *Biological Abstracts*, *Zoological Record*, and other indexing services. Manuscripts concerning research on the biota of the Northeast are especially invited for consideration.

THE PITCH PINE NATURALIST

The Pitch Pine Naturalist is the less formal journal published by the NEFNS. It functions as a means for members to publish primarily descriptive, nonanalytical notes and articles on the biota of the Northeast. Society announcements, book reviews, annual membership listings, membership requests, and other informal items are also included. Through the inclusion of their specialized ecological and regional natural history interests in the annual membership listing, members are able to stimulate appropriate contact with others.

CONSERVATION, REGIONAL PLANNING, AND PUBLIC INFORMATION PUBLICATION SERIES

The *Conservation, Regional Planning, and Public Information Publication Series* functions to bring important issues, particularly those relating to biological conservation in the Northeast, to the attention of ecologists, planners, conservationists, and the general public. Each number of this series concerns a specific aspect of biological conservation or general natural history(for example, a number may be devoted exclusively to the biotation of a region threatened with destruction by urbanization). Each number of the series is written in a biologically rigorous manner but is specifically designed to be understandable to the intelligent layman. Endangered natural populations and communities, alternative planning approaches, and sound biological conservation practices are emphasized. This series also serves to present important regional conservation issues that may otherwise remain overlooked by most biological conservationists and the general public. Although all members receive the series as part of their membership in the NEFNS, appropiate publicity is given to individual numbers, which are offered for sale to the general public.

MEMBERSHIP BENEFITS

All interested persons, regardless of whether or not they reside in the Northeast, are invited to become members of the NEFNS. As a member, you will receive *Engelhardtia*, *The Pitch Pine Naturalist*, the *Facsimile Reprint Series*, and the *Conservation, Regional Planning, and Public Information Publication Series*, and you will be welcome to submit suitable material for use in these periodicals.You will be listed with your special interests in field ecology and regional natural history in the annual membership listing published in *The Pitch Pine Naturalist*.

Individuals may become Regular Members ($6), Sustaining Members ($9), or Supporting Members ($15). All classes of membership are entitled to the same benefits; however, the extra funds provided by Sustaining and Supporting Members allow the Society to produce publications that would otherwise not be possible. Libraries, organizations, etc., may become Institutional Subscribers ($6). All dues and fees are payable on a calendar year basis.

Please send membership dues, subscription fees, and inquiries to the following address:

Northeastern Field Naturalists' Society
Post Office Box 6
Central Islip, Long Island, New York 11722

ANNOUNCEMENT

The Smithsonian Foreign Currency Program, a national research grants program, offers opportunities for support of research in Burma, Guinea, India, Pakistan, Poland (through 1976), and Egypt in the following disciplines:

Archeology and related disciplines (including Anthropology)
Systematic and Environmental Biology, Astrophysics and Earth Sciences, and Museum Programs

The program's appropriation for fiscal year 1977 totals $2,500,000 equivalent in the currencies of the above-listed countries. Grants in those currencies are awarded to American Institutions for the research of senior scientists. Collaborative programs involving host country institutions are welcome and frequently required. Awards are determined on the basis of competitive scientific review. The deadline for submission is November 1 annually. For further information write the Foreign Currency Program, Office of International Programs, Smithsonian Institution, Washington, D.C. 20560

"The Florida population of the American Crocodile, down to about a dozen breeding females and about 200 individuals, has been placed on the U.S. Dept. Interior's endangered species list. A Recovery Team has been appointed to develop a plan to restore this population to a secure status as a component of the South Florida ecosystem. Team members are Howard (Duke) Campbell (Team leader), Tommy Hines, Rich Klukas, James Kushland and John Ogden. The team is anxious to locate, 1) confirmed sightings of crocodiles out of the Everglades National Park in the last 5 years, and 2) all captive crocodiles which can be documented to have come from south Florida. Anyone with any pertinent information should write to Duke Campbell at: National Fish and Wildlife Laboratory, 2820 E. University Avenue, Gainesville, Florida 32601."

****

IN THE NEWS

The Florida game and fish commission has voted in principle to end a 10 year old ban on harvesting alligators for their hides. It is estimated that, in the past 10 years, the number of alligators has grown from an endangered level to over ½ million. Game officers receive over 10,000 alligator complaints a year and there have been six alligator attacks on humans in Florida in the last two years, including one fatal attack.

Milwaukee Journal

In Munich, Germany, city officials have come to the rescue of frogs that normally would get wiped-out trying to cross the Autobahn. A "help-a-frog-across-the-road" campaign has begun. The frogs are now being caught in buckets sunk in the ground and then transported across the Autobahn by volunteers. In addition, city officials hope "to build several tunnels under the highway at points corresponding to the centuries-old routes taken by the toads and frogs".

UPI in Milwaukee Sentinel

With financial assistance from the United Nations Development Program, pilot programs for crocodile farms are being organized in India. It has been estimated that one 500-mile area in West Bengal now earns $40,000 annually from forest products could yield as much as $12 million if formed into a crocodile preserve.

LOUIS J. PISTOIA (1917-1976)

Louis Pistoia, curator of reptiles at the Columbus (Ohio) Zoo, died of cancer on 9 May at the age of 58. Pistoia had been in charge of the reptile collection at Columbus since 1958, having previously been with the Staten Island and Bronx Zoos. During his tenure at Columbus he built the herpetological collection into probably the largest one in the United States, both in terms of the number of specimens and of species, rivalling the reptile collections of the larger zoos in New York, Philadelphia and Chicago. He also designed the innovative Reptilia-Amphibia Hall at the Columbus Zoo which was opened in 1968; this building was described in detail in an article by Pistoia in Herpetological Review, vol. 1, no. 3, pp. 4-6, 1968.

He was particularly well known for his many reptile longevity records, especially those for snakes, and for his ability to maintain a wide variety of species including many amphibians and other forms that are secretive, nocturnal or otherwise difficult to display. He was also successful in breeding programs and it is believed that more species of snakes were bred at the Columbus Zoo than at any other collection. Several species, in fact, have been captive bred there for four or five generations. In 1973, Pistoia received the Robert Bean Award from the American Association of Zoological Parks and Aquariums, specifically for breeding and raising Jamaican boas.

Cornell University announces SUMMER FIELD COURSES IN HERPETOLOGY AND ICHTHYOLOGY - June 29-August 12, 1977 . Also offered will be MAMMALOGY, ORNITHOLOGY, PLANT ECOLOGY, GENERAL ECOLOGY. For information write to Simon A. Levin, Chairman, Section of Ecology and Systematics,235 Langmuir Laboratory, Cornell University, Ithaca, NY 14853.

REGISTRY FOR REPTILE PATHOLOGY

Department of Veterinary Science
University of Maryland
College Park, Maryland
20742

PURPOSE: To broaden the field of Comparative Pathology by establishing a center where disease processes in reptiles will be studied and histopathological finding catalogued and maintained on file. The Department of Veterinary Science will also offer a service for diagnosis of disease problems on individual research animals or colony situations. A detailed report in findings will follow the submission of tissues or specimens.

PROCESSING: The attached necropsy sheet should be completed and history relevant to the case should be included. When possible, Kodachrome slides should be taken of all gross material. Tissues should be placed in buffered formalin for light microscopy. In addition, tissue samples should be placed in 2.5% glutaraldehyde for electron microscopy. Biopsy materials should be handled in the same way. If possible, a sterial swab (Culturete, Scientific Products) of the affected area should be included for microbial isolation. Representative samples from all major organ systems should be placed in separate containers of glutaraldehyde and formalin. Often tissues that fail to show gross lesions are of value for light and electron microscopic evaluation. All tissues should be as fresh as possible and should not be frozen.

WHERE TO SEND:

Dr. Elliott Jacobson
Dept. of Veterinary Sciences
University of Maryland
College Park, Maryland 20742
(Phone: 301 454-4651)

John W. Ferner, Asst. Prof. of Biology, Franklin & Marshall College, Lancaster, Pa. 17604 is preparing a manuscript on marking techniques for amphibians and reptiles and requests receipt of any unpublished methods.

Stephen Ayala, Helen Chin and John Simmons will be surveying Colombian lizard populations for malaria infections from July 1976-December 1977. Saurian reference collections will be deposited in Bogota, Cali and Medellin museums. An illustrated field guide to the lizards of Colombia is also planned. Participating institutions include the Universidad del Valle Medical School in Cali, INDERENA (Colombia's Natural Resources Institute), Peace Corps, University of Kansas Museum of Natural History, COLCIENCIAS (Colombian National Science Foundation) and the Tulane University International Center for Medical Research.

The small herpetological collection of the Museo Nacional de Costa Rica has recently been transferred to the Museo de Zoologia, Universidad de Costa Rica. The material is currently under study in order to ascertain its historical value. I would appreciate knowing of correspondence or other references to this material which may aid in deciphering partially destroyed labels, information regarding "lost" types, etc. The types of Haptoglossa pressicauda, Trimetopon viquezi and Pogonaspis ruficeps have not been found.

Stanley Dyrkacz is involved in an investigation of pattern striping in Lampropeltis calligaster. Anyone with information as to the disposition of specimens (especially living specimens for breeding purposes) should contact: S. Dyrkacz, Syntex Laboratories, 18 N. State Street, Elgin, IL 60120.

FEDERAL WILDLIFE PERMIT OFFICE ESTABLISHED

The U.S. Fish and Wildlife Service has announced the establishment of a new office "to implement an international treaty regulating commercial trade in and movement of the world's endangered wild plants and animals."

It will also be the task of the Federal Wildlife Permit Office to "ease the plight of scientists, zoos, and others who engage in activities involving federally protected wildlife by reducing red tape and simplifying the permit issuing process while maintaining needed controls...The Federal Wildlife Permit Office will first work toward coordination permits issued within the Fish and Wildlife Service, and later may become the coordinating body or clearing house for the issuance of all Federal permits involving wildlife."

The new office will be headed by Rick Parsons, an attorney. The address of the new office is:

U.S. Fish and Wildlife Service
Federal Wildlife Permits Office
Washington, D.C. 20240
Telephone 202-343-8916

CORNELL UNIVERSITY has available a position for a curatorial associate in Ichthyology and Herpetology. Experience with a systematic collection and formal training in Herpetology or Ichthyology, preferably both, is required. Applicants should send resumes and names of three referees to F. Harvey Pough, Associate Professor of Herpetology, Section of Ecology and Systematics, Cornell University, Ithaca, New York 14853.

CAUDATA

DESMOGNATHUS OCHROPHAEUS (Mountain dusky salamander). U.S.A., Vermont, Windsor Co., Stockbridge; 21 April 1962; J. D. Lazell, Jr. Museum of Comparative Zoology, MCZ 37796. First record for New England (Tilley, 1973, Cat. Amer. Amph. Rept., 129). Dr. Barry Valentine (in litt) acknowledged notification of the specimen's existence in 1962. Submitted by JAMES D. LAZELL, JR., Scientific Staff, Massachusetts Audubon Society, Lincoln, MA 01773.

GYRINOPHILUS PORPHYRITICUS (Spring salamander). U.S.A., Georgia, Upson Co., 11.7 km ESE Woodbury on Pine Mountain; 11 October 1975; Auburn University Museum, AUM 24032. Extends known range 143.6 km S from Bartow, Clark and Dekalb Cos., GA (Brandon, 1966, Illinois Biol. Monogr., 35:1-86; Reese, 1950, Chicago Acad. Sci. Nat. Hist. Misc., 63:1-7). Pine Mountain and adjacent Oak Mountain are discontinuous, parallel ridges isolated from areas of high relief to the north. This may indicate that suitable upland stream habitats are lacking in the intervening area. These ridges extend approximately 91.4 km ending 36.5 km north of the Fall Line. Submitted by THOMAS W. FRENCH, Dept. of Zoology-Entomology, Auburn University, Auburn, AL 36830.

PSEUDOTRITON MONTANUS DIASTICTUS (Midland mud salamander). U.S.A., Tennessee, Franklin Co., Sewanee; 14 April 1959; J. D. Lazell, Jr. Museum of Comparative Zoology, MCZ 31887 and collection of the University of the South, Sewanee, Tennessee, two untagged. Locality of within the range shown by Conant (1975, A Field Guide to Reptiles and Amphibians of Eastern and Central North America, Houghton Mifflin Co., Boston) but well outside that mapped by Martof (1975, Cat. Amer. Amph. Rept., 166). Specimens are typical of the subspecies diastictus, relegated to synonomy without explanation by Martof (op. cit.). Submitted by JAMES D. LAZELL, JR.

SALENTIA

RANA CATESBEIANA (Bullfrog). Mexico, Estudo de Baja California Sur, San Ignacio; 21 January 1974; D. A. Mullen. University of San Francisco Museum of Vertebrate Zoology, 5010-5017. Reported introduced by Americans in 1970. Now common in most local stock ponds . Extends range approximately 520 km S Colorado River drainage. Submitted by DAVID A. MULLEN, Dept. of Biology, University of San Francisco, San Francisco, CA 94117.

TESTUDINES

KINOSTERNON FLAVESCENS FLAVESCENS (Yellow mud turtle). Mexico, Tamaulipas, 7.7 km NW Manuel, Hwy 80; 24 Dec. 1973; M. E. Seidel. University of New Mexico, Museum of Southwestern Biology, UNM 30809. Extension of range below Tropic of Cancer and first record in the southern coastal plain of Tamaulipas. This locality is in a vegetation zone transitional between grassland and tropical forest (Leopold, 1950, Ecology 31(4):507-518) and represents a new ecological association for this species. Marshes and drainage ditches are abundant in the area. K. cruentatum was collected 20 km SE of the above locality and is probably sympatric with K. flavescens in this part of its range. Submitted by MICHAEL E. SEIDEL, Dept. of Biological Sciences,Marshall University, Huntington, WVA 25701.

SAURIA

OPHISAURUS COMPRESSUS (Island glass lizard). U.S.A., Florida, Taylor Co., 21 to 27 km W Perry on US 98; 29 May 1975; J. S. Godley and R. W. McDiarmid.

R. W. McDiarmid and J. S. Godley. University of South Florida, JSG 2785-2788. New county record; locality lies 196 km NE of St. George Island record (Blaney, 1971, Herpetologica, 24:418) and 222 km NW Cedar Key record(McConkey, 1954, Amer. Midl. Nat., 51:146). The new records suggests that the St. George Island population is not relictual (Blaney,op.cit.; Conant'75,A Field Guide to Reptiles and Amphibians of Eastern and Central North America, Houghton Mifflin Co., Boston) but rather the distribution of O. compressus may be continuous in the large tracts of suitable pineland habitat of this region. Submitted by J. STEVE GODLEY, Dept. of Biology, University of South Florida, Tampa, FL 33620.

SERPENTES

CEMOPHORA COCCINEA COPEI (Scarlet snake). U.S.A., Arkansas, Izard Co., 18.3 km W Melbourne; 13 May 1971; W. Byrd and E. L. Hanebrink. Arkansas State University, ASU 1293. Sharp Co., 5.2 km W Cave City; 3 July 1974; W. Byrd and E. L. Hanebrink. ASU 1294. Extends range in the Ozarks of northcentral Arkansas. These records fill the gap between previous collected specimens in Arkansas and the isolated records of Nickerson (1967, Herpetol., 23:74) and Williams and Wilson (1967, Tulane Stud. Zool., 13:103-124). Submitted by WILLIAM BYRD and EARL L. HANEBRINK, Division of Biological Sciences, Arkansas State University, State University, AR 72467.

DIADOPHIS PUNCTATUS ARNYI (Prairie ringneck snake). U.S.A., Oklahoma, Lincoln Co., 3.2 km NE Aydelotte; 1 March 1975; J. Short and J. Black. Oklahoma Baptist University, Webster Natural History Museum, WNHM 101. New county record and completes range to include all counties in central Oklahoma (Webb, 1970, Reptiles of Oklahoma, Univ. Oklahoma Press). Submitted by JEFFERY HOWARD BLACK and JEFFERY SHORT, Dept. of Biology, Oklahoma Baptist University, Shawnee, OK 74801.

HETERODON NASICUS GLOYDI (Dusty hognosed snake). U.S.A., Arkansas, Polk Co., Skyline Drive on top of Rich Mountain at western boundary of Queen Wilhelmina State Park; 27 June 1975; D. B. Means, J. B. Atkinson, G. H. Means. Florida State Museum collection, UF/FSM-34, 807. First state record for species; extends range (by disjunction?) about 391.5 km from western Oklahoma or northeastern Texas (Conant, 1975, A Field Guide to Reptiles and Amphibians of Eastern and Central North America, Houghton Mifflin Co.). Submitted by D. BRUCE MEANS, Tall Timbers Research Station, Route 1, Box 160, Tallahassee, FL 32303.

SEMINATRIX PYGEA PALUDIS (Carolina swamp snake). U.S.A., South Carolina, Chesterfield Co., Carolina Sandhills National Wildlife Refuge, 12.4 km W McKennon; 6 Sept. 1975; J. S. Garton, B. L. Sill, L. Olmsted. W. Palmer. North Carolina State Museum, NCSM 15893. Extends known range west into the inner Coastal Plain in northern South Carolina. Submitted by JOHN S. GARTON and BEN L. SILL, Civil-Environmental Division, Duke Power Company, Box 2178, Charlotte, NC 28242.

STILOSOMA EXTENUATUM (Short-tailed snake). U.S.A., Florida, Highlands Co., 12 km S Lake Placid; 6 October 1975 and 15 April 1976; W. M. Masters and J. F. Douglas. Archbold Biological Station, uncataloged. First records for county; extend known range 78 km SW of previous southernmost locality (Brimley, 1910, Proc. Biol. Soc. Wash., 23:9-18). Habitats: sand pine scrub and slash pine-turkey oak woods. Submitted by JOHN F. DOUGLASS, Archbold Biological Station, Route 2, Box 180, Lake Placid, FL 33852.

STORERIA DEKAYI TEXANA (Texas brown snake). U.S.A., Oklahoma, Woodward Co., 9.7 km NW Woodward on US Hwy 183-270; 18 August 1975; C. J. and J. K. McCoy. C. J. McCoy. Carnegie Museum 60495. New westernmost record in Oklahoma(Webb, 1970, Reptiles of Oklahoma, Univ. Oklahoma Press). Submitted by CLARENCE J. McCOY, JR., Carnegie Museum, 4400 Forbes Ave., Pittsburg, PA 15213.

THAMNOPHIS RADIX HAYDENI (Western plains garter snake). U.S.A., Oklahoma, Woodward Co., 6.5 km NW Woodward on US Hwy 183-270; 18 August 1975; C. J. and J. K. McCoy. C. J. McCoy. Carnegie Museum 60462. Eastward range extension, first record outside panhandle in Oklahoma (Webb, 1970, Reptiles of Oklahoma, Univ. Oklahoma Press). Submitted by CLARENCE J. McCOY, JR.

TROPIDOCLONION LINEATUM (Lined snake). U.S.A., Oklahoma, Harper Co., 33.4 km N Woodward (Woodward Co.) on St. Hwy 34; 16 August 1975; C. J. and J. K. McCoy. C. J. McCoy. Carnegie Museum 60465. Fills distributional gap between Kingfisher Co. to the east and the Black Mesa area to the west. (Webb, 1970, Reptiles of Oklahoma, Univ. Oklahoma Press). Submitted by CLARENCE J. McCOY, JR.

OPHEODRYS VERNALIS BLANCHARDI (Western smooth green snake). U.S.A., Iowa, Story Co., 4.1 km SW Gilbert (SW¼, S18, T84N, R24W); 25 Aug. 1974; W.F. Hollander; Iowa St. Univ. Collection, ISU 2880. Using color standards of Ridgeway (1912, Washington, D.C., 1-43), supralabials, chin and venter light buff in live specimen. Above supralabials, head showed an abrupt transition to buffy brown. First scale row tilleul buff darkening to buffy brown by fourth scale row. Carroll Co., Coon Rapids; July 1939; Iowa St. Univ. Collection, ISU 432. Preserved specimen is grey-brown, similar to preserved specimen described by Grobman (1941, Misc. Pub. Mus. Zool., Univ. Michigan, 50:1-38). Reports of buff-colored specimens of O. vernalis were summarized by Collins and McDuffie (1963, J. Ohio Herp. Soc.4:22). They cite nine specimens, two O. v. vernalis from northern Michigan and 7 O. v. blanchardi from the Chicago, Illinois area. This report is the first record of this variation in O. v. blanchardi outside the Chicago area and extends the known range of its occurrence westward by approximately 450 km. We thank J.L. Christiansen for reviewing the manuscript. Submitted by PAUL J. HOLLANDER, R.R. 4, Ames, IOWA 50010 and M.CHRISTOPHER BARNHART, 1000 Pammel Ct., Ames, IOWA 50010.

DISTRIBUTIONAL RECORDS OF SOME REGIONALLY UNCOMMON SNAKES. The following records are presented in view of their relative scarcity in the regions concerned:

CEMOPHORA COCCINEA COPEI (Scarlet snake). U.S.A., Oklahoma, Payne Co., 20 km W Stillwater; 24 April 1969; D.C. Stairs. R.L. Lardie. Oklahoma St. Univ. R 3600. Specimen collected 33 km N of most westerly known locality in Logan Co. (Webb, 1970, Reptiles of Oklahoma, U. Okla. Press).

LAMPROPELTIS TRIANGULUM AMURA (Louisiana milk snake). U.S.A., Texas, Parker Co., 6 km N Aledo; 11 April 1965; R.L. Lardie. R.L. Lardie. Fort Worth Museum of Science and History, previously RLL 523 in collection of R.L. Lardie. County record and supplements Raun and Gehlbach (1972, Amphibians and Reptiles in Texas, Dallas Mus. Nat. Hist. Bull. No. 2).

RELICT POPULATIONS OF PITUOPHIS MELANOLEUCUS AND THAMNOPHIS RADIX IN ILLINOIS. The following recent records confirm the statements of Hurter (1903 , St. Louis Acad. Sci. Trans., 13(3):77-86), Smith (1961, Illinois Nat. Hist. Surv. Bull., 28(1):1-298) and Stull (1940, USNM Bull. 175:1-225) that relictual populations of these two species may occur in the Madison - St. Clair Co., Illinois area. Individuals are still common where preferred habitat is available.

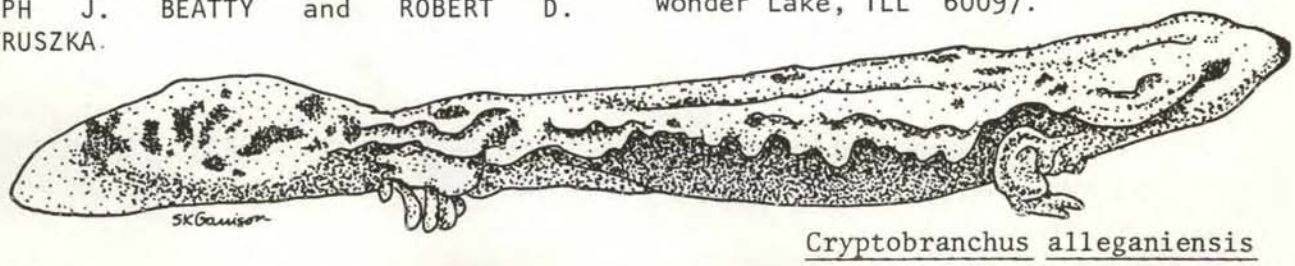
PITUOPHIS MELANOLEUCUS SAYI (Bullsnake). St. Clair Co., Rairview Heights; 10 April and 2 May 1970; G. McNaughton. Illinois Nat. Hist. Surv. Collection, INHS 9902-3 and collection of G. McNaughton, GM 003. Caseyville; 14 April 1971; G. McNaughton. Collection of G. McNaughton, alive (3).

THAMNOPHIS RADIX RADIX (Eastern plains garter snake). St. Clair Co., Caseyville; 14 April 1971; G. McNaughton. Collection of G. McNaughton, GM 1914-6. Submitted by GENE McNAUGHTON, 55 Circle Creek Dr., Cahokia, ILL 62206.

CAUDATA

MANCULUS QUADRIDIGITATUS (Dwarf salamander). U.S.A., North Carolina, Vance Co., 10.4 km E Henderson; 12 March 1975 and 26 May 1975; A.L. Braswell. D. L. Stephan and A.L. Braswell. North Carolina State Museum of Natural History NCSM 14805, 3 adults; NCSM 14806, 29 larvae; NCSM 15168, 22 larvae. Extends range 44 km N of previous northernmost locality (N.C., Wake Co., 10.2 km ENE Rolesville, NCSM 12696, 3 larvae), and within 39 km of the Virginia border. Submitted by D. L. STEPHAN, Dept. of Entomology, North Carolina State University, Raleigh, N.C. 27607 and A.L. BRASWELL, North Carolina State Museum of Natural History, Box 27647, Raleigh, N. C. 27611.

PLETHODON ELONGATUS (Del Norte salamander). U.S.A., Oregon, Coos Co., 11.2 km S Powers; 20 April 1975; Oregon State University Herpetology class. OSU Museum of Natural History, OSU 10,712-15 (4 specimens). Extends range 12.0 km N of previous northern limit (Brodie,1970, Herpetologica 26(4)). Submitted by ROBERT M. STORM, JOSEPH J. BEATTY and ROBERT D. PIETRUSZKA, Dept. of Zoology, Oregon State University, Corvallis, OR 97331.



PLETHODON VEHICULUM (Western red-backed salamander). U.S.A., Oregon, Coos Co., 11.3 km SE Powers; 20 April 1975; OSU Herpetology Class. OSU Museum of Natural History, OSU 10, 716-23 (8 specimens). Extends range 6.4 km SE of previous southeastern limit (Brodie, 1970, Herpetologica 26(4)). This report, with the one above, sharply reduces the zone of allopatry between these two Plethodon. The apparent separation of these two species is thus reduced to a 2.4 km section along Road 333 which runs south from Powers to Agnes. Submitted by ROBERT M. STORM, JOSEPH J. BEATTY and ROBERT D. PIETRUSZKA.

SALIENTIA

BUFO ALVARIUS (Colorado river toad). Mexico, Baja California Norte, Mexicali, 9.2 km W (J.F. Allen 255-257) and 9.8 km W (R.S. Funk); 5 June 1963; J.F. Allen, C. H. Croulet and R.S. Funk. Only published Baja California locality is 7.6 km N El Mayor, ca. 72 km south (Brattstrom, 1951, Herpetologica 7(4)). Submitted by RICHARD S. FUNK, Dept. of Biological Sciences, Illinois State University, Normal, IL 61761 and CURTIS H. CROULET, 7791 Gribble St., San Diego CA 92114.

BUFO WOODHOUSEI (Woodhouse's toad). Mexico, Baja California Norte, Mexicali, 9.2 km W and 9.8 km W (J.F. Allen 243-253); 5 June 1963; J.F. Allen, C.H. Croulet and R.S. Funk. Only published Baja California locality is Stebbins (1951, Amphibians of Western North America, p. 502) at lat. 32°15'N near Laguna Salada, S Mexicali (Stebbins, pers. comm.). One of us (RSF) has found this toad to be abundant at Algodones, but no specimens were preserved. Submitted by RICHARD S. FUNK and CURTIS H. CROULET.

GASTROPHRYNE CAROLINENSIS (Eastern narrow-mouthed toad). U.S.A., Illinois, Union Co., near Bluff Lake; 3 June 1969; D. Becker. University of Wisconsin, Stevens Point Collection, UWSP 858. Jackson Co., bank of Mississippi River in Grand Tower; 1 June 1969; D. Becker. P. W. Smith. UWSP 888. Confirms existence in extreme southern Illinois. Specimens were collected between the Mississippi River bluff population and the extreme southeastern Missouri population (Nelson, 1972, J. Herpet. 6:111-137). These, along with the Scott Co., MO record (Dyrkacz, 1973, HISS News-J. 1:152), further decrease this long established hiatus. Submitted by STANLEY DYRKACZ, 3012 Walnut Drive, Wonder Lake, ILL 60097.

Cryptobranchus alleganiensis

NEW COUNTY RECORDS AND RANGE EXTENSIONS OF SOME WEST TEXAS REPTILES. The following records for Texas reptiles supplement those of Raun and Gehlbach (1972, Dallas Mus. Nat. Hist., Bull. No. 2) and Hambrick (1975, Herp. Rev. 6 (3):79-80). Specimens in this report are deposited in the Museum of Arid Land Biology (MALB), University of Texas at El Paso, El Paso, Texas and the Department of Biology, Sul Ross State University (SRSU), Alpine, Texas.

NEW COUNTY RECORDS. Testudines: Kinosternon flavescens, Midland Co. (MALB 2660). Sauria: Crotaphytus collaris, Midland Co. (SRSU 3634); Holbrookia maculata maculata, Midland Co. (MALB 2663-2674); Sceloporus undulatus consobrinus, Midland Co. (MALB 2662); Uta stansburiana, Midland Co. (MALB 2675). Serpentes: Leptotyphlops dulcis, Midland Co. (MALB 2661); Diadophis punctatus arnyi (collected by M. Erskine), Howard Co. (MALB 2852); Masticophis flagellum (collected by W. Tucker), Midland Co. (MALB 2793); Pituophis melanoleucus sayi, Midland Co. (MALB 2853); Sonora episcopa (collected by S. Wilkinson), Midland Co. (MALB 2792).

RANGE EXTENSION. Cnemidophorus sexlineatus, July, 1975; (MALB 2790, SRSU 3636). Establishes another local population approximately 100 km northwest of the nearest one in Reagan Co. Cnemidophorus tigris, Midland Co. approx. 16 km SE Midland; 7 June 1975; (SRSU 3635). Extends range approximately 30-50 km eastward from Ector Co. Submitted by JOHN M. CYS, P.O. Drawer 2437, Midland, TX 79701.

NEW HERPETOFAUNAL RECORDS FOR ILLINOIS. The following records supplement those of P. W. Smith (1961, The amphibians and reptiles of Illinois, Ill. Nat. Hist. Surv. Bull. 28(1):1-298). All specimens are deposited in the Illinois Natural History Survey collection (INHS).

Amphibia: Plethodon cinereus cinereus (Red-backed salamander). Champaign Co., 1.6 km NW Homer; 2-10 December 1972; J. D. Unzicker. INHS 10048. County record and westernmost Illinois locality for the species. Desmognathus fuscus conanti (Spotted dusky salamander). Pulaski Co., 1.2 km NE Olmsted; 16 July 1975; M. A. Morris and L. M. Page. INHS 10204. Reported as extirpated in Illinois by Dyrkacz (1974, Bull. Chicago Herp. Soc. 9(1-2):15-16). Siren intermedia nettingi (Western lesser siren). Bond Co., 0.6 km NE Pocohontas; 7 July 1973; B. M. Burr and R. D. Wrisberg. INHS 10043. County record. Moultrie Co., 1.5 km NW Allenville; 1 July 1965; D.L. Thomas. INHS 9743. Extends known siren range in Kaskaskia River valley ca. 125 km NE Bond Co. record. Rana sylvatica (Wood frog). Edwards Co., 0.6 km S Browns; 10 July 1962; M. E. Braasch. INHS 9614. County record. Gastrophryne carolinensis (Eastern narrow-mouthed toad). Hardin Co., Rosiclare; 13 August 1962; R. D. Gustafson. INHS 9613. First record for southeastern Illinois.

Reptilia: Ophisaurus attenuatus attenuatus (Western slender glass lizard). Cass Co., Virginia Township; May 1970; J. Calhoun. INHS 9827. Lee Co., 3.6 km N Ohio; 12 July 1972; M. D. Jackson. INHS 9842. County records. Lampropeltis triangulum syspila (Red milk snake). Clark Co., Lincoln Trail State Park; 8 October 1972; M. A. Morris. INHS 9959. County record and first hatchling syspila (190 mm total length, 164 mm SVL) reported for Illinois. Natrix erythrogaster flavigaster(Yellow-bellied water snake). Pike Co., W Pleasant Hill; 4 October 1966; R. A. Evers and L. J. Stannard. INHS 10230. Substantiates occurrence of this form in the county. Virginia valeriae elegans (Western smooth earth snake). Coles Co., 2.4 km SSE Rardin; 6 June 1968; P. W. Smith and L. M. Page. INHS 9803. 40 km NW of nearest record;

demonstrates penetration past the Shelbyville Moraine into a predominantly prairie region. Submitted by MICHAEL A. MORRIS, Illinois Natural History Survey, Urbana, IL 61801.

GEOGRAPHIC RECORDS OF SOME SOUTH TEXAS AMPHIBIANS AND REPTILES. This paper adds to the county records and range extensions reported by Raun and Gehlbach (1972, Amphibians and Reptiles in Texas, Dallas Mus. Nat. Hist., Bull. No. 2), Lewis (1974, Herp.Rev. 5(1):21), Merkord (1975, Herp. Rev. 6(3):79), and Hambrick (1975, Herp. Rev. 6(3):79-80). All specimens are in the Texas Cooperative Wildlife Collection, Texas A & M University, College Station, Texas. Identification are by the authors.

NEW COUNTY RECORDS. Bufo debilis, Maverick Co. (TCWC 49050); Rana catesbeiana, Medina Co. (TCWC 49034); Cophosaurus texanus, Zavala Co. (TCWC49068); Sceloporus variabilis, Maverick Co. (TCWC 48893); Scincella laterale, Uvalde Co. (TCWC 49167); Crotalus lepidus, Bandera Co. (TCWC 49228); Drymarchon corais, Medina Co. (TCWC 49201); Elaphe guttata, Uvalde Co. (TCWC 49194); Elaphe obsoleta, Uvalde Co. (TCWC 49195); Lampropeltis getulus, Zavala Co. (TCWC 49199); Leptotyphlops dulcis, Uvalde Co. (TCWC 49189); Rhinocheilus lecontei, Medina Co. (TCWC 49209).

RANGE EXTENSION RECORDS. Pseudacris clarki, Uvalde Co., 13 mi N Uvalde; 22 May 1975; C. M. Mather, TCWC 49061). The nearest records are for Atascosa, Bexar and Dimmit Counties. Syrrhophus cystignathoides, Bexar Co., San Antonio; 20 May 1973; C. M. Mather, TCWC 48105-48106. Probably represents an introduced colony, as nearest records are Cameron Co. and Hidalgo Co., Texas. Anolis carolinensis, Uvalde Co., Uvalde; 19 April 1975; C. M. Mather, TCWC 49103. Probably introduced because it was found only in residential areas of the city. The nearest record is Bexar County. Elaphe subocularis, Uvalde Co., 8.3 mi N Uvalde; 3 July 1975; C. M. Mather, TCWC 49196. The nearest records are for Edwards and Val Verde Counties. Thamnophis cyrtopsis, Uvalde Co., 13 mi N Uvalde; 11 June 1975; C. M. Mather, TCWC 49216. The nearest records are for Bandera, Medina and Real Counties. Submitted by CHARLES M. MATHER and JAMES R. DIXON, Dept. Wildlife and Fisheries Sci., Texas A & M University, College Station, TX 77843.

NOTES ON THE OCCURRENCE OF THE LIZARD, TROPIDURUS TORQUATUS (WEID), IN ARGENTINA. Conflicting statements have been reported concerning the range of Tropidurus torquatus (Weid). Burt and Burt (1931) reported on specimens housed in the collection of the American Museum of Natural History from Cruz del Eje, Provincia de Cordoba and from Chaco (presumably Provicia de Chaco)Argentina. Peters and Donoso-Barros (1970) restricted the range of this species to Brazil and the Guianas. Rand and Rand (1966) reported it from these localities, but also included Venezuela in its range. The American Museum specimens reported by Burt and Burt (1931) have been examined by me and are indeed Tropidurus torquatus. In addition seven specimens of this species were collected during the 1974-75 field season from a locality 10 km E Chamicel, Provincia de La Rioja, Argentina. This is approximately 152 km W of the Cruz del Eje locality. Several other specimens conforming to Tropidurus torquatus were observed in Parque de Nacional de Iguazu, Provincia de Misiones along the Argentina-Brazilian border. These records, plus the American Museum specimens confirm the existence of T. torquatus in Argentina.

The Chamicel specimens were collected in the transitional zone between the Dry Chaco and the Monte Desert in a wash dominated by Prosopis chiliensis, Acacia aroma, and Boulnesia sp. The lizards were never found in the open Larrea flats where trees were absent. When approached they would attempt to escape into trees or into burrows in the root systems of the trees. One female

collected in December 1974 contained seven enlarged follicles. The specimens from Parque Nacional de Iguazu were found associated with rocky outcroppings on an island in the Rio Parana. When approached these lizards would escape into cracks in the rocks. Habitat preference and escape patterns from both localities conform to those described by Rand and Rand (1966) for a population of T. torquatus in Belem, Brazil.

GEOGRAPHIC DISTRIBUTION

TESTUDINES

KINOSTERNON SUBRUBRUM SUBRUBRUM X K.S. HIPPOCREPIS (Eastern x Mississippi mud turtle). U.S.A., Illinois, Alexander Co., Olive Branch, 1 mile E Horseshoe Lake Conservation Area; 8 June 1974; S. Dyrkacz and R. Herrington. S. Dyrkacz. Collection of S. Dyrkacz, SD 91. Third intergrade specimen from Alexander Co. on northern edge of distribution. See Cahn (1937, Ill. Biol. Monog. 16 (1-2): 1-218) and Skorepa and Ozment (1968, Trans. Ill. Acad. Sci. 61 (3) :247-251). Carapace length 85 mm. Submitted by STANLEY DYRKACZ, 3012 Walnut Drive, Wonderlake, Illinois 60097.

SALENTIA

RANA CATESBEIANA (Bullfrog). Mexico, Baja California Norte, Mexicali, 9.8 km W (J.F. Allen 254); 5 June 1963; J. F. Allen, C. H. Croulet and R. S. Funk. Algodones (R. S. Funk 3540); 13 Aug. 1970; R. S. Funk. First records from Baja California Norte east of Sierra de Juarez; known from west of this range and from adjacent Imperial Co., CA and Yuma Co., AZ, U.S.A. (Stebbins, Field Guide to Western Amphibians and Reptiles map 53). Stebbins (pers. comm.) has indicated he knew of no specific records from NE Baja CA. Over a several year period (1962-1970), one of us (RSF) has heard calls of this frog in Baja CA along the Colorado River between Algodones and a locality ca. 8 air km NW Riito, Sonora, and also at Campo Rio Hardy on the Rio Hardy (ca. 19 km S La Puerta on Mex. Hwy. 5), but no specimens were collected. Submitted by RICHARD S. FUNK and CURTIS H. CROULET.

JOB OPENING - MUSEUM TECHNICIAN

We anticipate an opening for a museum technician in the Division of Reptiles and Amphibians by the time this announcement appears.

The job consists of physical curation and technical management of the amphibian and reptile collection, together with other duties related to museum work, such as maintenance of the Divisional Library and responding to inquiries from the public and professional herpetologists. This is not a research position, but does require a person with a knowledge of and interest in amphibians and reptiles. The position starts at $8,900.00/year.

If the position opens as anticipated, we need to fill the position quickly or lose it. Our deadline for having job applications on hand is 5 November 1976.

Need Reptile Identification Tags?

Kimball Systems has them!

Kimball Systems is THE source for reptile identification tags...and Kimball has more than 100 years of experience in making tags of every kind.

With Kimball, you can be certain that your tags will be made to precise specifications and rigid standards of quality. They can be printed on one or both sides, in non-soluble and waterproof inks . . . on a broad range of impervious and solvent-resistant stocks . . . and can also be consecutively numbered.

Kimball Systems Product Representatives are located coast-to-coast. They will be happy to discuss your tag requirements and offer practical suggestions. Just contact the address below.

NOTICE

OPENING FOR EDITORSHIP HERPETOLOGICAL REVIEW

At the end of this calendar year, Dr. Max Nickerson will be terminating his Editorship of HERPETOLOGICAL REVIEW. The SSAR is currently seeking a replacement to assume this important function.

HERPETOLOGICAL REVIEW is the quarterly News-letter publication of the society. The editor is responsible for all phases of operations relating to publication and distribution. Specifically, this includes selection of section editors, soliciting advertising, scheduling printing, billings, setting up for printing and distribution, as well as other relevant tasks.

Persons who may be interested in being considered for the Editorship are requested to submit their names to Dr. Nickerson, Vertebrate Division, Milwaukee Public Museum, Milwaukee, Wisconsin 53233, accompanied by a statement as to the resources available to assist them in publication activities. The deadline for consideration of candidates will be 25 July, 1976. Appointment of the new Editor will be made by the SSAR officers during the 1976 annual meetings in August.

EDITOR'S NOTE

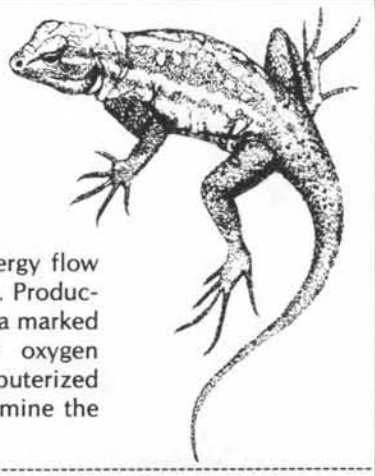
The enormous response to the SSAR/HL meetings at Miami University of Ohio this August has forced us to print a double sized issue of Herpetological Review. Additionally, all normally scheduled sections and papers have been reassigned to HR 7(3). The role of Herpetological Review is clearly stated in the SSAR Constitution and SSAR business and functions are published on a priority basis. We are most pleased with the enthusiastic response to the forthcoming meetings but are chagrined by the inconvenience which some authors will suffer.

M.A.N.

LAST CHANCE FOR REDUCED PRICES!

HOLBROOK'S

NORTH AMERICAN HERPETOLOGY



The Society's reprint of this natural history classic will be issued in October 1976. Since only a limited number of copies will be printed, orders must be placed in advance. Special discounts are offered to SSAR members *only if orders are received by 15 August*. Two editions will be produced:

REGULAR EDITION: Clothbound. . . . . before 15 August, $50; later, $60

PATRON'S EDITION: Edition limited to 150 copies specially bound in leather to match Holbrook's originals *plus a separate set of the 20 colored plates* for framing. The names of all patrons will be recorded on a page in both editions . . . . . before 15 August, $150; later, $175

A fuller description of both editions and a sample color plate were published in the last issue of *Herpetological Review*, vol. 7, no. 1 (March) following page 16. Orders can be placed with Dr. Seibert (see last page)

ENERGY UTILIZATION BY A DESERT LIZARD (*UTA STANSBURIANA*)

by F. B. Turner, P. A. Medica and B. W. Kowalewsky. 57 pp.

US/IBP Desert Biome Monograph No. 1
Published by Utah State University Press, April 1976

This monograph is the culmination of a detailed three-year study of energy flow through a field population of the side-blotched lizard in southern Nevada. Production values are based on cohort weights recorded at frequent censuses of a marked population. Respiratory energy loss is derived from estimates of oxygen consumption based on body weight and body temperature. A basic computerized simulation providing the best representation of reality is tested to determine the simplest predictor of energy flow.

ORDER FORM

Please send _____ copies of "Energy utilization by a desert lizard (*Uta stansburiana*)" at $1.00 each to:

LOCH NESS MONSTER EVIDENCE PRESENTED AT CORNELL UNIVERSITY

On May 4th, an audience of 1500 Cornell faculty and students examined the most recent photographic and sonar evidence for the existence of large unidentified animals in Scotland's Loch Ness. It was the first time that these data had been presented publicly and then opened to critical evaluation by a group of scientists. Although the event was covered by Associated Press and received international syndication, it was felt that a more detailed published account with some of the original data would be of value, and especially because of its potential special interest to the herpetological community.

The purpose of the program was to provide a forum for a long-overdue public examination of the evidence by scientific experts, but it was also intended as an educational device to demonstrate for students the ways in which science approaches new discoveries which, by their very nature, are often on the edge of believability. The lecture was presented by Charles W. Wyckoff, president of Applied Photo Sciences, Inc., of Needham Heights, Massachusetts. Mr. Wyckoff, a widely-respected inventor of wide-exposure-range films, is the photographic consultant to the Loch Ness Project sponsored by the Academy of Applied Science of Boston. Mr. Wyckoff's lecture was followed with a panel discussion by distinguished Cornell faculty, among them several members of the U. S. National Academy of Sciences and including experts in remote sending, imagery, vertebrate anatomy, paleontology, and biology. I organized the event and served as moderator.

Mr. Wyckoff's Lecture

Mr. Wyckoff began by giving a description of Loch Ness, the largest body of fresh water in the British Isles. It is about 24 miles long, 1.5-2 miles wide, and has a nominal depth of 700 feet, although depths of 975 feet have been recorded;the sides of the Loch are quite steep (Fig. 1). The waters are cold year-round, varying by only a few degrees from about 42°F. The water has a yellow-brown color due to large quantities of suspended peat particles which reduce underwater visibility to a few feet. Wyckoff's group has worked primarily in Urquhart Bay along the west shore of the loch since this area accounted for the largest number of sightings of the monster over the last several decades. Furthermore, the beasts are thought to feed on salmon that regularly congregate in Urquhart Bay before migrating upstream to spawn.

The first recorded sightings of a "monster" in Loch Ness was by St.Columba in 565 A.D. After the construction of a modern road along the west side of the lake in the 1930's the number of reported sightings increased dramatically but, as Mr. Wyckoff pointed out, there were a number of hoaxes and several photographs were obvious fakes. Perhaps the most famous of the supposedly authentic photographs is the "surgeon's photograph" (Fig. 2) taken in 1934 but, typical of surface photographs, it is a silhouette and shows no detail;furthermore, Mr. Wyckoff noted that there is no sense of scale.

The present series of photographs and sonar data was obtained by members of the Loch Ness Project sponsored by the Academy of Applied Science, a private organization of several hundred scientists, inventors and industrialists devoted to the support of unusual areas of research. The Project is led by Dr. Robert H. Rines,a Boston patent attorney and Dean of the Franklin Pierce Law Center in New Hampshire. In 1972 they obtained the famous "flipper" photographs, together with a simultaneous sonar record (Fig. 3). But as Wyckoff noted, these photographs suffer from the back-scatter of light

from suspended peat particles and the photos, therefore, required computer enhancement, a process that sharpens an image but does not falsify the record.

In order to minimize the light-scattering problem during the 1975 season, Wyckoff separated the light source from the camera (Fig. 4) and further improved the system by using a sonar-gated signal that turned on the cameras only when a target of sufficient size came within camera view. These techniques were successful in producing the dramatic color photographs in Plate I, which, according to Wyckoff and his colleagues, show various portions of the head, neck and body of one of the creatures.

After last summer's work the Rines-Wyckoff group made plans to present their data to zoologists at a meeting organized by the Royal Society to be held in Edinburgh last December. But at the last minute the meeting was cancelled by the organizers due to premature adverse publicity that was precipitated by the publication of a revised edition of Witchell's "The Loch Ness Story" which contained a detailed description of the 1975 data but no photographs. At the same time, the Rines group was further criticized for publishing a formal scientific name for the Loch Ness Monster (Nessiteras rhombopteryx Scott and Rines, 1975). But, as Wyckoff noted, the sole purpose of this article was to facilitate full protection for the beast in the event that its existence was proved since, under British law, protection can be granted only to organisms having a scientific name. Nevertheless, a confidential presentation of the data was made by the group to a joint committee of both Houses of Parliament and protection now seems assured.

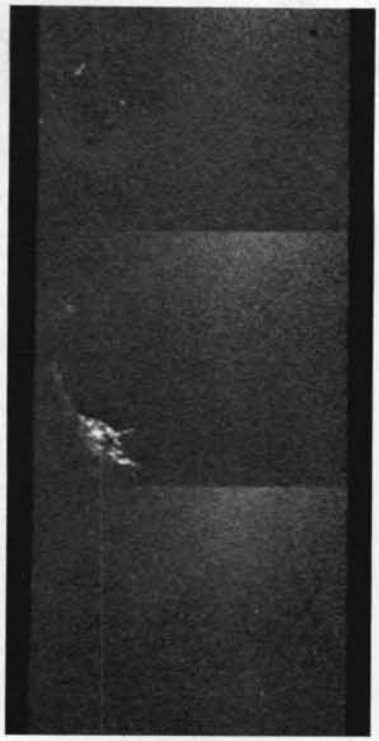
Wyckoff concluded his lecture by saying that this summer's expedition will use the same equipment as before, but also underwater television directed at the cameras so that any disturbance of the apparatus by the beast can be witnessed. Furthermore, they will be using high-resolution sonar in order to locate any skeletal remains on the silty bottom of the loch before recovering them. He noted that although they have succeeded in overcoming much of the stigma of ridicule, they have had to support the entire operation from their own private funds.

The Panel Discussion

After Mr. Wyckoff's lecture, six Cornell faculty were invited to the stage to make comments on the data and to question the speaker. Each had been given copies of the data in advance; only the more substantive points are recorded here.

Dr. Melvin L. Kreithen, a specialist in vertebrate sensory physiology, pointed out that the greatest strength of the approach used by Wyckoff and his colleagues is that three different modalities are involved simultaneously: photographic, sonar and the mechanical disturbance of the cameras (Plate I). Kreithen asked if the sonar records could be caused by sound echoing off of thermoclines, but Wyckoff noted that at the observation site the thermoclines were at depths of several hundred feet, well beyond the range of the cameras.

Dr. Thomas Eisner, a behavioral ecologist, asked why hydrophones had not been used to detect possible sounds made by the beasts. He pointed out that sounds undoubtedly are made when the camera is disturbed or simply when any object moves past the cameras. Furthermore, in the murky waters of the Loch, it seems reasonable to expect any large, widely-spaced-out animals to use echolocation to find prey and mates. Wyckoff answered that hydrophones had indeed been used, that there were no positive results and they were discontinued after the 1971 season. Nevertheless, he now feels that the sound frequency spectrum was too narrow



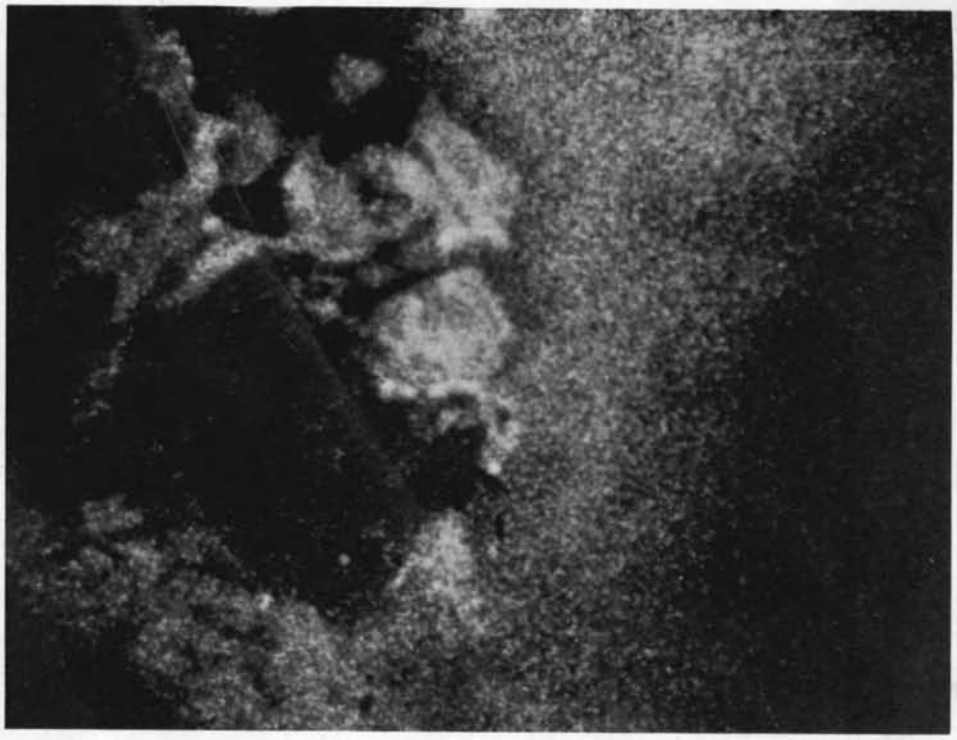


PLATE I (A) Photograph taken at 4:32 AM, 20 June 1975, purportedly of the upper body, neck and head; note absence from adjacent frames taken at 1.2 min intervals from center shot. Light cone and densitometric measurements indicate that "body" was at distance of 25 ft and "neck" was about 10 ft long.

(B) Photograph taken at 11:45 AM, 20 June 1975, showing "head". This series of six frames (intervals, 1.2 min) records a period of major disturbance, with the camera swinging upward; note bottom of boat, length 20 ft. The center shot, enlarged at right, is interpreted by Wyckoff's group as the head, showing bilateral symmetry in half-profile; note the mouth and nostrils at right and the several horn-like protrusions. An interpretive drawing by Sir Peter Scott is shown at bottom. The "head" was about 5 ft from the camera and is estimated to be 2 ft long. Camera-strobe arrangement for all photos in plate I is shown in fig. 4. (All photographs copyright Academy of Applied Science)

and that these experiments should be repeated.

Dr. Donald J. Belcher, an authority on remote sensing data, made an interesting point concerning the "surgeon's photo" (Fig. 2). He noted that the beast appears to have set up a series of refractory waves that interrupt the entire wave pattern surrounding it. This would imply that the object had a considerable mass and tends to rule out the common criticism that it is merely a bird or some other small object.

Dr. Howard E. Evans, an anatomist and authority on aquatic vertebrates, stated that he had no doubt that the photos were of living creatures but he interpreted them to be a giant sturgeon, noting the existence of the white sturgeon of Russia which reaches a length of 24 feet. Evans suggested that Plate IA might be the tail-end of a sturgeon, and the "head" in IB the mouth-parts of an upside-down sturgeon in which the so-called "tentacles" are simply barbels. The failure to recover any skeletal remains could be accounted for by the fact that these fish are cartilaginous and perhaps only the dermal plates would become fossilized. Finally, he suggested that the concentration of monster sightings in Urquhart Bay might be due to its use as a sturgeon spawning site rather than a place to capture migrating salmon. Wyckoff remarked that sturgeon have never been reported anywhere in the British Isles, but that they had already considered this possible interpretation of their photographs and rejected it.

Dr. Carl E. Sagan is an astronomer and is noted for his work on the Mariner probes of Venus and Mars, projects involving some of the same photographic enhancement techniques used in the Loch Ness Project. Sagan stated that the possibility of a hoax in this instance is quite remote because of the reputations of the persons involved and because of the elaborateness necessary to perpetrate a hoax when the data-gathering techniques are so sophisticated and involve so many simultaneous modalities. He also remarked that he had contacted his associates at the Jet Propulsion Laboratory in Pasadena, California, where the Loch Ness photos had been processed and they are convinced of the photographs' authenticity. Sagan felt that the Rines-Wyckoff data, although not definitive, were the best hard evidence now available and cause him to believe that large unidentified organisms do exist in Loch Ness.

Sagan then mentioned his recent calculation of the possible number of monsters in Loch Ness, based on the mean-free-time method of collision physics. A rough measure of the number can be calculated based on the collision distance (the camera's range), the organism's velocity and the average time between encounters. His estimate of a number of beasts is "between several tens and several hundreds"(Sagan, 1976), with an average separation distance between animals of about 0.4 km. He said that the number density estimate is, interestingly, about the same as that derived by completely independent means based on biomass calculations that assume a diet of fish (Sheldon and Kerr, 1972). Wyckoff added that if we assume that each of the half dozen locations where sightings are most numerous represent a "family group", then the total number of individuals in Loch Ness may similarly be in the same range of values.

Dr. John W. Wells, a geologist and paleontologist, stated that during the Pleistocene Loch Ness was filled to the bottom with ice since it has the typical transverse profile of a glaciated valley. Since the ice receded about 12,000 years ago, any monsters must have come in from the sea after that time. Wells said it was highly unlikely that any Mesozoic marine reptiles such as Plesiosaurs could have done so since there are no fossil records beyond the Mesozoic, and that all species were tropical in distribution He suggested that the

beasts may be fish and noted the discovery of the carcass of a basking shark on the shore of Loch Ness in 1942.

Concerning the new photographs, Wells thought that some of them looked like old logs whose rapid movement in and out of camera view (Plate I) could be accounted for by the passage of internal waves which cause no surface movement, yet involve a very considerable transfer of energy. Wyckoff noted that in one of the photographs a cylindrical object with a diameter of 6-8 ft was observed, yet there are no trees in the vicinity of Loch Ness today having diameters in excess of 4 ft. Wells countered with the suggestion that the submerged trunks could have been remnants of the very large trees of the great Caledonian Forest of Scotland, which burned down within historic times.
